Supporting Information

ABSTRACT: We report the apparently unprecedented direct reaction of nitric oxide (NO) with amides to generate ions of structure $R(C=O)NH-N(O)=NO^-$, with examples including $R = Me$ (**1a**) or 3-pyridyl (**1b**). The sodium salts of both released NO in pH 7.4 buffer, with 37 °C half-lives of 1–3 min. As NO-releasing drug candidates, diazeniumdiolated amides would have the advantage of generating only 1 equiv of base on hydrolyzing exhaustively to NO, in contrast to their amine counterparts, which generate 2 equiv of base.

Many secondary and primary amines react with nitric oxide (NO) to generate products of structure $R^1R^2N-N(O)-N=O^-$, known as diazeniumdiolate ions. Extensive structure/reactivity studies involving a wide variety of amines were carried out by the Drago research group a half a century ago,^{1,2} showing the remarkable generality of this amine-derivatizing reaction. Interestingly, they did not describe any attempts to react the corresponding amides with NO, nor have we seen any such reports in the intervening literature. We have long taken this absence of relevant prior literature as a tacit suggestion that attempts to diazeniumdiolate an amide by directly reacting it with NO would probably be fruitless, until now continuing our focus on the amine/NO adducts that have proven so useful as biomedical research tools and potential clinical entities.^{3–9}

Here we show that this skepticism was unfounded by reporting on the direct reaction of NO with amides under basic conditions to produce novel ionic diazeniumdiolates, an apparently unprecedented transformation (see eq 1).

with an ultraviolet absorbance maximum at 252 nm, consistent with the presence of a diazeniumdiolate group¹⁰ [i.e., a group of structure $X-N(O)=NO^-$] and suggesting that the reaction had led to diazeniumdiolate ion **1a**, as in eq 1.

The product proved relatively stable in basic solutions but decomposed on lowering the pH to 7.4 with a half-life at 37 °C of 1.2 min. Abundant NO was seen as a gaseous product of this reaction. In addition, significant yields of nitrite ion were observed. The results for the nitrogenous products are summarized in Table 1. The organic products were analyzed by NMR of the spent reaction mixture. Acetamide was detected in 78% yield, and the sodium acetate yield was close to 22%.

Similar results were seen when the experiment was repeated using nicotinamide instead of acetamide. Again, the product was stable in base but on neutralization smoothly lost its UV peak at 250 nm, suggestive of the diazeniumdiolate structure **1b** with a half-life of 2.8 min at pH 7.4 and 37 °C. The relative distribution of nitrogenous products was similar to that seen in the case of acetamide in that they are primarily NO and nitrite, though in this case, some N_2O was seen (Table 1). Nicotinamide was recovered in 55% yield, similarly to that of the NO (52%) and nicotinic acid (45% of theory).

The two ionic amide diazeniumdiolates can be compared to the primary amine analogue IPA/NO (Scheme 1), where the acyl groups of ions **1** are replaced with an alkyl residue. Although the

Treatment of methanolic acetamide with 3 atm of NO in the presence of sodium methoxide led to deposition of a white solid

three compounds have similar stability profiles, they differ greatly in the relative yields of their nitrogenous products (Table 1). As presented above, both **1a** and **1b** primarily generate NO and nitrite with very little N₂O production. In contrast, IPA/NO decomposes via two pathways running in parallel; the minor pathway regenerates starting materials from its synthesis (isopropylamine + 2 equiv of NO), while the major pathway produces a mole each of HNO and isopropanediazoate ion.¹¹

The ionic primary amine diazeniumdiolate IPA/NO can be dialkylated in two successive steps, first at the terminal O and then at the amine N.¹³ Ion **1a** can also be dialkylated, but it differs from IPA/NO in that the intermediate monoalkyl species could not be isolated. An additional difference between **1a** and IPA/NO is that the former could theoretically be alkylated at the amide oxygen, a functionality absent in IPA/NO (Scheme 2). No evidence for alkylation at that position was seen, however, as X-ray crystallography confirmed the *O,N*-dialkylated structure **2** in Scheme 2.

Scheme 2. Benzylation of Ion **1a** Produced the *O,N*-Dialkylated Derivative **2** (*O,O'*-Dialkylated Structure Was Not Observed)

Salt **1b** could be dialkylated with methyl iodide and benzyl bromide (Scheme 3). To our surprise, the dialkylation products isolated after normal aqueous workup, which we expected to have structure **3**, contained no halide ion, as evidenced by mass spectrometry and absence of a precipitate on addition of the silver(I) ion to their aqueous solutions. Molecular weight measurements of the dibenzyl products suggested that the N–H proton had been lost during workup, forming zwitterions **4b** and **4b'**, as shown in Scheme 3, and this was confirmed by X-ray crystallography of the dibenzyl derivative.

We were surprised to find no prior literature documenting a successful reaction of NO directly with an amide. The only product of such a hypothetical reaction that we could locate had the constitution of *N*-diazeniumdiolated acetanilide ion, but it was reportedly generated in a radical-mediated side reaction in

Scheme 3. Diazeniumdiolation of Nicotinamide, Followed by Dialkylation To Form Zwitterions **4**

the decomposition of *N*-nitrosoacetanilide.¹⁴ (Several *N*-diazeniumdiolated carbamates have also been prepared by routes that bypassed the ionic structure **1** by first *O*-alkylating the terminal oxygen of IPA/NO to make a neutral species and then acylating the NH group.)^{15,16}

Mechanistically, by analogy with the pathways established for the primary amine diazeniumdiolates, we assume that the decomposition of ions **1** consists of two general mechanisms, one being a major, or in the case of **1a** exclusive, pathway leading to regeneration of the two NO molecules, with the starting amide being the organic product. A concurrent pathway, minor for **1b** but not seen for **1a**, begins with cleavage of HNO (followed by its dimerization to N₂O) and production of an acyldiazoate ion (which hydrolyzes to the carboxylic acid/carboxylate with loss of N₂), as shown in Scheme 4.

From the observed stoichiometry, **1a** appears to dissociate exclusively by the NO release pathway shown at the top of Scheme 4, as no N₂O was detected. The NO and acetamide yields were roughly similar, as anticipated (88 and 78%,

Scheme 4. Proposed Mechanisms of Dissociation of Diazeniumdiolated Amide Ions **1** at Physiological pH (See Salmon et al.¹¹ for a Full Mechanistic Description of IPA/NO Hydrolysis, Including pH Effects)

respectively). The 22% acetate yield was not expected according to this mechanism but could have arisen by nitrosative deamination of the remaining acetamide or by simple hydrolysis. In contrast, dissociation of **1b** did produce some N_2O (7%), indicating a role for the lower pathway of Scheme 4; however, the upper route producing NO and nicotinamide remained the dominant path, the products being recovered in yields of 52 and 55%, respectively.

An advantage of diazeniumdiolated amides relative to the widely used secondary amine diazeniumdiolates as NO donors is that the former's exhaustive decomposition in neutral buffer consumes only 1 equiv of acid while the amine derivatives consume 2 equiv (Scheme 5). Thus, the decomposition of

Scheme 5. Hydrolysis of Diazeniumdiolated Amines To Produce NO Consumes Two Protons, While That of the Corresponding Amide Derivatives Consumes Only One

diazeniumdiolated amides produces a nonbasic amide, while exhaustive hydrolysis of secondary amine diazeniumdiolates produces a still basic amine that consumes an additional proton. This property would be especially beneficial in a biomedical setting, where careful pH control is essential.

The results suggest that a variety of useful NO-releasing hybrid drugs might be forthcoming from a systematic study of reactions of different bioactive amides with NO as described above.

EXPERIMENTAL SECTION

Caution: IPA/NO and certain other diazeniumdiolates have shown a tendency to dissociate rapidly and unexpectedly and hence should be handled with due care.

General. Ultraviolet (UV) spectra were recorded on a diode array spectrophotometer. Nuclear magnetic resonance (NMR) spectra were collected with a 400 MHz spectrometer using appropriate deuterated solvents with chemical shifts reported in parts per million downfield from tetramethylsilane or 2,2,3,3-tetradeuteriotrimethylsilylpropionic acid. Ions for high-resolution mass spectrometry were generated with electrospray ionization and detected with a quadrupole time-of-flight mass analyzer.

Purity Measurements for Salts **1a and **1b**.** Ionic diazeniumdiolates are notoriously difficult to purify, so it is correspondingly problematic to provide quantitative data on the properties of the above-identified products. Nevertheless, rough purity estimates could be derived from NMR experiments using internal standards in alkaline solutions. The result for **1a** using potassium phthalimide as internal standard was a purity level of 50%, with the remainder presumably consisting of NaOH and other UV- and NMR-silent constituents. The purity of the **1b** sample was similarly determined to be 80% using *tert*-butyl alcohol as internal standard. These values were used as normalization factors to establish the extinction coefficients as well as theoretical yields of the various products summarized in Table 1.

Sodium 1-(*N*-Acetylamino)diazen-1-ium-1,2-diolate (1a**).** A solution of 5.9 g (0.1 mol) of acetamide in 21.7 mL (0.1 mol) of 4.6 M methanolic sodium methoxide, 10 mL of methanol, and 50 mL of diethyl ether was charged with 40 psi of nitric oxide and stirred under pressure at room temperature. A precipitate began to be visible within 2 h; stirring was continued overnight, giving a thick white precipitate. The

precipitate was collected by filtration, washed with acetonitrile, and dried under vacuum to give 3.07 g of a white powder that was 50% pure according to the NMR/internal standard method described above (10% yield). As a further purification step, 2 g of crude **1a** (50% pure, 7.1 mmol) was dissolved in 100 mL of methanol and stirred at room temperature. The methanolic solution was treated with 100 mL of ether, giving a white solid that was collected by filtration and triturated with acetonitrile, then dried in vacuo to give 1.7 g of product. This process removed most of the acetamide contaminant: UV (in 0.01 M NaOH) λ_{max} 252 nm ($9.7 \text{ mM}^{-1} \text{ cm}^{-1}$); ^1H NMR ($\text{D}_2\text{O}/\text{NaOD}$) δ 1.68 (s); ^{13}C NMR ($\text{D}_2\text{O}/\text{NaOD}$) δ 20.8, 177.1.

Sodium 1-(*N*-Nicotinoylamino)diazen-1-ium-1,2-diolate (1b**).** A solution of 9.1 g (0.075 mol) of nicotinamide in 30 mL of methanol was treated with 15.2 mL (0.07 mol) of 4.6 M methanolic sodium methoxide. To the solution was added 50 mL of ether, after which the vessel was degassed and charged with 50 psi of nitric oxide. The solution was stirred at room temperature; after 72 h, the pressure was released and the white precipitate was collected by filtration. The solid was washed with acetonitrile and dried under vacuum to give 3.91 g of **1b** (80% pure by the internal standard NMR method described above, 20% yield) as a powder: UV (0.01 M NaOH) λ_{max} 250 nm ($11.8 \text{ mM}^{-1} \text{ cm}^{-1}$); ^1H NMR ($\text{D}_2\text{O}/\text{NaOD}$) δ 7.50–7.56 (m, 1H), 8.23–8.28 (m, 1H), 8.59–8.63 (m, 1H), 8.93–8.96 (m, 1H); ^{13}C NMR ($\text{D}_2\text{O}/\text{NaOD}$) δ 123.8, 132.6, 136.4, 147.7, 150.0, 171.4.

Reaction of **1a with Benzyl Bromide To Form **2**.** To a slurry of 252 mg of **1a** (0.89 mmol) and 250 mg of anhydrous sodium carbonate in 10 mL of DMF at 0 °C was added 438 μL (3.6 mmol) of benzyl bromide; the resulting slurry was stirred at 0 °C with gradual warming to room temperature. After being stirred overnight, the reaction mixture was cooled to –80 °C and placed in a lyophilizer; on evaporation, the solid residue was extracted with dichloromethane. The organic layer was dried over sodium sulfate, filtered through a layer of magnesium sulfate, and evaporated to give 229 mg of an oil. The crude product was chromatographed on a 25 g silica gel column and eluted with a gradient from 100% methylene chloride to 70:30 methylene chloride/ethyl acetate to give 102 mg (38%) of pure **2**: mp 57–58 °C; UV (ethanol) λ_{max} 244 nm ($11.1 \text{ mM}^{-1} \text{ cm}^{-1}$); ^1H NMR (CDCl_3) δ 7.35 (s, 3H), 4.92 (s, 2H), 5.18 (s, 2H), 7.23–7.34 (m, 10H); ^{13}C NMR (CDCl_3) δ 19.8, 49.8, 76.7, 128.3, 128.6, 128.6, 128.7, 128.9, 129.0, 133.8, 134.9, 169.1; HRMS (ESI) m/z calculated for $\text{C}_{16}\text{H}_{18}\text{N}_3\text{O}_3^+$ m/z ($\text{M}^+ + \text{H}^+$) 300.13427, measured 300.1350. Anal. Calcd for $\text{C}_{16}\text{H}_{17}\text{N}_3\text{O}_3$: C, 64.20; H, 5.72; N, 14.04. Found: C, 64.18; H, 5.81; N, 14.29.

Reaction of **1b with Benzyl Bromide To Form **4b**.** A slurry of 1.54 g of 80% pure **1b** (6.1 mmol) in 20 mL of *N,N*-dimethylformamide was reacted with benzyl bromide (1.19 mL, 0.01 mol) under conditions similar to those used to prepare **2** (previous paragraph) to give 420 mg (19%) of pale brown solid. The product was recrystallized from hot water to give white X-ray quality crystals of **4b**: mp 236–8 °C; UV (in 1:1 $\text{H}_2\text{O}/\text{CH}_3\text{CN}$) λ_{max} 239 nm ($11.9 \text{ mM}^{-1} \text{ cm}^{-1}$); ^1H NMR ($\text{DMSO}-d_6$) δ 5.07 (s, 2H), 5.90 (s, 2H), 7.33–7.52 (m, 10H), 8.10 (t, 1H) $J = 7.4$ Hz, 8.88 (d, 1H) $J = 7.8$ Hz; ^{13}C NMR ($\text{DMSO}-d_6$) δ 63.1, 73.0, 127.7, 127.9, 128.1, 128.3, 128.8, 129.3, 129.3, 134.4, 137.1, 139.0, 143.7, 143.8, 144.7, 162.6; HRMS (ESI) m/z calculated for $\text{C}_{20}\text{H}_{19}\text{N}_4\text{O}_3^+$ 363.14517, measured m/z 363.14567. Anal. Calcd for $\text{C}_{20}\text{H}_{18}\text{N}_4\text{O}_3 \cdot 0.25\text{H}_2\text{O}$: C, 65.47; H, 5.08; N, 15.27. Found: C, 65.62; H, 4.84; N, 15.54.

Reaction of **1b with Dimethyl Sulfate To Form **4b'**.** Compound **1b** (1.34 g, 80% pure, 5.3 mmol) was dissolved in 50 mL of cold methanol (0 °C) and reacted with dimethyl sulfate (1.52 mL, 16 mmol) as above to give 1.8 g of an orange oil. The resulting crude product was chromatographed on silica gel using a gradient from 100% dichloromethane to 50:50 dichloromethane/methanol as the eluent. A fraction containing 296 mg of product was concentrated, whereupon the residual oil crystallized on standing. Recrystallization from methanol gave 259 mg (23%) of analytically pure **4b'**: mp 202–205 °C; UV (H_2O) λ_{max} 239 nm ($4.9 \text{ mM}^{-1} \text{ cm}^{-1}$) and λ_{max} 268 nm ($3.3 \text{ mM}^{-1} \text{ cm}^{-1}$); ^1H NMR (D_2O) δ 4.11 (s, 3H), 4.62 (s, 3H), 8.11 (br s, 1H), 8.89 (br s, 2H), 9.21 (br s, 1H); ^{13}C NMR (D_2O) δ 51.2, 64.0, 130.6, 138.9, 146.5, 147.6, 149.2, 170.0; HRMS (ESI) m/z calculated for $\text{C}_8\text{H}_{11}\text{N}_4\text{O}_3^+$ m/z 211.08257, measured 211.08338. Anal. Calcd for $\text{C}_8\text{H}_{10}\text{N}_4\text{O}_3 \cdot 0.25\text{H}_2\text{O}$: C, 44.75; H, 4.93; N, 26.10. Found: C, 44.62; H, 4.85; N, 25.75.

Kinetic Studies. Kinetic experiments were performed at 37 °C using a standard UV–visible spectrophotometer. Reactions were initiated by addition of substrate to a preheated cuvette containing the buffer. Analyte concentration was measured in 100 μ M 0.1 M phosphate buffer, pH 7.4, containing 50 μ M diethylenetriamine pentaacetic acid (DTPA). In each experiment, the data were analyzed at the λ_{max} and the rate was derived by fitting the data to an exponential curve typical for first-order processes.

Analysis for NO. Chemiluminescence detection and quantification of NO evolving from the reactions were conducted using a commercial nitric oxide analyzer. A pH 7.4 solution of 0.1 M phosphate buffer with 50 μ M DTPA was sparged with inert gas until a steady detector response was established. Compound **1a**, **1b**, or IPA/NO was added to a final concentration of 100 μ M, and the NO release profile was followed over time after injection. The resulting curve was integrated to quantify the amount of NO released/mol of compound.

Griess Assay Test for Nitrite Detection. Each reaction was allowed to proceed to completion, according to the protocol above, in the absence of purging with inert gas. We then added 100 μ L of Griess reagent, 300 μ L of sample, and 2.6 mL of deionized water together in a spectrophotometer cuvette. We incubated the mixture for 30 min at room temperature and prepared a reference sample by mixing 100 μ L of Griess reagent and 2.9 mL of deionized water. The absorbance of the nitrite-containing sample at 548 nm relative to the reference sample was converted to nitrite concentrations using a calibration curve.

N₂O Measurements by Gas Chromatography. Reactions were run according to the conditions stated above. The gas chromatography was performed using an electron capture detector, equipped with a ⁶³Ni 370 MBq source. A packed column (2 m \times 2.0 mm i.d.) was used with helium as the carrier gas. The GC operation conditions were as follows: injector and detector temperatures were at 250 °C; oven temperature was programmed from 90 to 200 °C at 20 °C/min and held at 200 °C for 1.1 min; helium flow was 30 mL/min; and nitrogen was used as make-up gas at 2 mL/min.

Organic Product Analysis. The organic products of the aqueous decomposition of **1a** and **1b** were analyzed by NMR upon exhaustion of the nitrogenous products in a deuterated phosphate buffer under the conditions listed above.

X-ray Crystal Data on Compounds **2 and **4b**.** Single-crystal X-ray diffraction data on compounds **2** and **4b** were collected using Mo K α radiation and a Bruker APEX-2 CCD area detector. Crystals were prepared for data collection by coating with high viscosity microscope oil. The oil-coated crystal was mounted on a micromesh mount and transferred to the diffractometer. The structures were solved by direct methods and refined by full-matrix least-squares on F^2 values using the programs found in the SHELXTL suite (Bruker, SHELXTL v6.10, 2000, Bruker AXS Inc., Madison, WI). Corrections were applied for Lorentz, polarization, and absorption effects. Parameters refined included atomic coordinates and anisotropic thermal parameters for all non-hydrogen atoms. Hydrogen atoms on carbons were included using a riding model (coordinate shifts of C applied to H atoms) with the C–H distance set at 0.96 Å. Complete information on data collection and refinement is available in the Supporting Information.

For compound **2**, a 0.256 \times 0.047 \times 0.011 mm³ crystal was prepared for data collection and a data set collected at 150 K. The crystal was triclinic in space group $P\bar{1}$, with unit cell dimensions of $a = 5.429(4)$ Å, $b = 8.743(5)$ Å, $c = 16.342(11)$ Å, $\alpha = 96.30(3)^\circ$, $\beta = 96.60(3)^\circ$, and $\gamma = 92.33(3)^\circ$. Data were 92.5% complete to $23.30^\circ \theta$ (~ 0.90 Å, the limit of diffraction for this crystal) with an average redundancy of 1.35. The final anisotropic full-matrix least-squares refinement on F^2 with 201 variables converged at $R1 = 7.72\%$ for the observed data and $wR2 = 24.35\%$ for all data.

For compound **4b**, a 0.258 \times 0.184 \times 0.058 mm³ crystal was prepared for data collection and a data set collected at 150 K. The crystal was monoclinic in space group $C2/c$, with unit cell dimensions of $a = 18.3109(19)$ Å, $b = 10.8087(9)$ Å, $c = 20.0132(16)$ Å, and $\beta = 109.785(4)^\circ$. Data were 99.6% complete to $28.33^\circ \theta$ (~ 0.73 Å) with an average redundancy of 4.22. The final anisotropic full-matrix least-squares refinement on F^2 with 244 variables converged at $R1 = 4.54\%$ for the observed data and $wR2 = 14.23\%$ for all data.

Atomic coordinates for **2** and **4b** have been deposited with the Cambridge Crystallographic Data Centre (deposition numbers 1015513 and 1015514, respectively). Copies of the data can be obtained, free of charge, on application to CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK [fax: +44(0)-1223-336033 or e-mail: deposit@ccdc.cam.ac.uk].
