S Supporting Information

ABSTRACT: Photocatalytic oxygenation of 10-methyl-9,10-dihydroacridine (AcrH₂) by dioxygen (O₂) with a manganese porphyrin [(P)Mn^{III}: 5,10,15,20-tetrakis-(2,4,6-trimethylphenyl)-porphyrinatomanganese(III) hydroxide [(TMP)Mn^{III}(OH)] (**1**) or 5,10,15,20-tetrakis(pentafluorophenyl)porphyrinatomanganese(III) acetate [(TPFPP)Mn^{III}(CH₃COO)] (**2**)] occurred to yield 10-methyl-(9,10H)-acridone (Acr=O) in an oxygen-saturated benzonitrile (PhCN) solution under visible light irradiation. The photocatalytic reactivity of (P)Mn^{III} in the presence of O₂ is in proportion to concentrations of AcrH₂ or O₂ with the maximum turnover numbers of 17 and 6 for **1** and **2**, respectively. The quantum yield with **1** was determined to be 0.14%. Deuterium kinetic isotope effects (KIEs) were observed with KIE = 22 for **1** and KIE = 6 for **2**, indicating that hydrogen-atom transfer from AcrH₂ is involved in the rate-determining step of the photocatalytic reaction. Femtosecond transient absorption measurements are consistent with photoexcitation of (P)Mn^{III}, resulting in intersystem crossing from a triplet excited state to a triplexet excited state. A mechanism is proposed where the triplexet excited state reacts with O₂ to produce a putative (P)Mn^{IV} superoxo complex. Hydrogen-atom transfer from AcrH₂ to (P)Mn^{IV}(O₂^{•−}) generating a hydroperoxo complex (P)Mn^{IV}(OOH) and AcrH[•] is likely the rate-determining step, in competition with back electron transfer to regenerate the ground state (P)Mn^{III} and O₂. The subsequent reductive O–O bond cleavage by AcrH[•] may occur rapidly inside of the reaction cage to produce (P)Mn^V(O) and AcrH(OH), followed by the oxidation of AcrH(OH) by (P)Mn^V(O) to yield Acr=O with regeneration of (P)Mn^{III}.

INTRODUCTION

High-valent metal–oxo complexes are the reactive oxidants in the oxidation of various substrates with heme and nonheme iron enzymes.^{1–6} Synthetic high-valent metal–oxo complexes have been prepared using oxidants such as peroxy acids, iodosylarenes, and hydrogen peroxide, and the mechanisms of oxidation of substrates by high-valent metal–oxo complexes have been studied extensively.^{7–12} High-valent metal–oxo complexes have also been produced by using dioxygen (O₂) with reductants.^{13–18} Among various high-valent metal–oxo complexes, high-valent manganese–oxo complexes have attracted special attention because they are postulated as important intermediates for water oxidation in the oxygen-evolving center (OEC) of photosystem II.^{19–27} A well-characterized manganese(V)–oxo complex has been prepared by oxidation of a manganese(III) corrolazine [(TBP₈Cz)Mn^{III}; TBP₈Cz^{3−} = octakis-(*p*-*tert*-butylphenyl)corrolazinato^{3−}] with O₂ in the presence of toluene derivatives under visible light irradiation.^{28,29} The (TBP₈Cz)Mn^{III} complex also acts as a photocatalyst for oxidation of 10-methyl-9,10-dihydroacridine (AcrH₂) by O₂.²⁹ However, there has been no report on photocatalytic oxidation of substrates by O₂ using manganese porphyrins.

We report herein the photocatalytic oxidation of AcrH₂ by O₂ with manganese(III) porphyrins [(P)Mn^{III}: (TMP)-

Mn^{III}(OH) (**1**: TMP^{2−} = dianion of tetramesitylporphyrin) and (TPFPP)Mn^{III}(CH₃COO) (**2**: TPFPP^{2−} = dianion of 5,10,15,20-tetrakis(pentafluorophenyl)porphyrin)] (Chart 1) under visible light irradiation in O₂-saturated benzonitrile (PhCN) at room temperature. The photocatalytic reactivity of manganese porphyrin complexes is compared with that of (TBP₈Cz)Mn^{III}. The photocatalytic mechanism of oxidation of AcrH₂ by O₂ with (P)Mn^{III} is investigated based on kinetic studies and laser flash transient absorption measurements to clarify the photoinduced reaction mechanism of (P)Mn^{III} with O₂.

EXPERIMENTAL SECTION

Materials. The (TMP)Mn^{III}(OH) was synthesized according to published procedures.³⁰ The (TPFPP)Mn^{III}(CH₃COO) complex was prepared by the following procedures. First, 5,10,15,20-tetrakis(pentafluorophenyl)porphyrin (0.10 g) from Sigma-Aldrich Co., manganese(II) acetate (0.96 g) from Wako Pure Chemical Industries, Ltd. and DMF (25 mL) were placed in a round-bottomed flask (50 mL). After the mixture was refluxed and stirred for 6 h, the solvent was removed under

reduced pressure to yield 0.245 g of crude (TPFPP)-Mn^{III}(CH₃COO) as a dark solid that was used without further purification. 10-Methyl-9,10-dihydroacridine (AcrH₂) was prepared by reduction of 10-methylacridinium perchlorate (AcrH⁺ClO₄⁻, Tokyo Chemical Industry Co., Ltd.) with NaBH₄.³¹ PhCN was distilled over P₂O₅ in vacuo and stored under an argon atmosphere prior to use.³²

Photocatalytic Reaction. The reactivity of photocatalytic oxygenation of manganese(III) complexes, **1** or **2** (1.0×10^{-5} M), with AcrH₂ and O₂ was evaluated by monitoring the UV–vis absorption spectral change in a quartz cuvette (10 mm × 10 mm). Visible light irradiation was carried out by a xenon lamp (500 W) through a transmitting glass filter ($\lambda < 480$ nm). In a typical experiment, **1** or **2** (1.0×10^{-5} M) was dissolved in PhCN (2.0 mL) containing AcrH₂ ($0\text{--}2.0 \times 10^{-1}$ M) in the quartz cuvette. The mixture was degassed by bubbling O₂ gas for 10 min, and then, the reaction was initiated by irradiating the solution with a xenon lamp transmitting through a color glass filter ($\lambda > 480$ nm). The electronic absorption spectral changes during photocatalytic oxygenation of **1** or **2** were monitored using a Hewlett–Packard HP8453 diode array spectrophotometer. The yield of Acr=O produced was calculated by an increase in the absorption band at 402 nm ($\epsilon_{\text{max}} = 8.6 \times 10^3 \text{ M}^{-1} \text{ cm}^{-1}$) in PhCN due to Acr=O.³³

Quantum Yield Determination. A standard actinometer (potassium ferrioxalate)³⁴ was used to estimate the quantum yield of the photochemical oxidation of **1** (1.0×10^{-5} M) with O₂ and AcrH₂ ($0\text{--}1.5 \times 10^{-1}$ M) in PhCN (2.0 mL). Typically, a square quartz cuvette (10 mm × 10 mm) that contained an O₂-saturated PhCN solution (2.0 mL) of **1** (1.0×10^{-5} M) and AcrH₂ was irradiated with a Panther OPO pumped Nd:YAG laser (Continuum, SLII-10, 4–6 ns fwhm) at $\lambda = 476$ nm. Typical pulse energies for the photoexcitation of the sample solution were in the range of 10 mJ per pulse. Under the conditions of actinometry experiments, the actinometer and **1** absorbed essentially all of the incident monochromatized light at 476 nm. The light intensity at 476 nm was 1.8×10^{-9} einstein s⁻¹. The quantum yields were estimated by monitoring the appearance of absorbance at 402 nm ($\epsilon_{\text{max}} = 8.6 \times 10^3 \text{ M}^{-1} \text{ cm}^{-1}$) due to Acr=O.

Femtosecond Laser Flash Photolysis Measurements. Measurements of transient absorption spectra of **1** and **2** were carried out according to the following procedures. An O₂- or N₂-saturated PhCN solution containing **1** (4.0×10^{-5} M) or **2** (8.0×10^{-5} M) was excited by a femtosecond laser pulse at 393 nm using an ultrafast laser source, Integra-C (Quantronix Corp.),

and a second harmonic generation (SHG) unit, Apollo (Ultrafast Systems, U.S.A). The optical detection system Helios was also provided by Ultrafast Systems. The detailed instrumental setting is shown in the Supporting Information.

Kinetic analyses were assembled from the time-resolved spectral data. The decay rate of the tripquintet (⁵T₁) of manganese(III) porphyrin obeyed the first-order kinetics given by eq 1

$$\Delta\text{Abs} = A_1 \exp(-k_1 t) + A_2 \quad (1)$$

where A_1 is the pre-exponential factor for the absorption changes, A_2 is the final absorbance, and k_1 is the rate constant of the decay of the tripquintet (⁵T₁) after femtosecond laser pulse irradiation. The slower decay rate of the tripseptet (⁷T₁) also obeyed the first-order kinetics given by eq 2, where A_3 is the final absorbance at 565 nm and k_2 is the rate constant of the decay of ⁷T₁.

$$\Delta\text{Abs} = A_1 \exp(-k_1 t) + A_2 \exp(-k_2 t) + A_3 \quad (2)$$

RESULTS AND DISCUSSION

Photocatalytic Oxidation Reaction of AcrH₂ by O₂ with (P)Mn^{III}X. The photocatalytic oxidation of 10-methyl-9,10-dihydroacridine (AcrH₂) by O₂ with (P)Mn^{III}X was performed by photoirradiation of an O₂-saturated PhCN solution containing AcrH₂ and (TMP)Mn^{III}(OH) (**1**) or (TPFPP)-Mn^{III}(CH₃COO) (**2**) using a xenon lamp (500 W) with a transmitting glass filter ($\lambda > 480$ nm). The absorption spectral changes in the photocatalytic oxidation of AcrH₂ by O₂ with **1** and **2** are shown in Figures 1a and b, respectively. The absorption spectra of **1** and **2** remained during the photocatalytic reaction, whereas the absorption band at $\lambda_{\text{max}} = 402$ nm ($\epsilon_{\text{max}} = 8.6 \times 10^3 \text{ M}^{-1} \text{ cm}^{-1}$) due to 10-methyl-(9,10H)-acridone (Acr=O) appeared and the concentration of Acr=O increased linearly with photoirradiation time. The turnover numbers were determined to be 17 and 6 for **1** and **2** at 5 h of photoirradiation. It was confirmed that no formation of Acr=O was observed in the absence of O₂ or the light source [see Figures S1 and S2 in the Supporting Information (SI)]. It should be noted, however, that the direct photo-oxidation of AcrH₂ by O₂ occurred under photoirradiation without a glass filter.³⁵ The stoichiometry of the photocatalytic oxidation of AcrH₂ by O₂ is given by eq 3.

Figure 1. UV-vis absorption spectral changes and time course of formed Acr=O (inset) in an O₂-saturated PhCN solution (2.0 mL) containing (a) (TMP)Mn^{III}(OH) (1.0×10^{-5} M) or (b) (TPFPP)-Mn^{III}(CH₃COO) (1.0×10^{-5} M) and AcrH₂ (2.0×10^{-1} M) under visible light irradiation ($\lambda > 480$ nm).

Kinetics. Rates of formation of Acr=O in the photocatalytic oxidation of AcrH₂ with **1** in O₂-saturated PhCN were monitored by an appearance in the absorbance at 402 nm due to Acr=O under photoirradiation using a xenon lamp with a transmitting glass filter ($\lambda < 480$ nm) at 298 K. The initial reaction rate of the photocatalytic oxidation of AcrH₂ by O₂ in Figure 2a was determined to avoid the effects of changes in the

Figure 2. (a) Plots of the formation of Acr=O during the photocatalytic oxygenation of AcrH₂ under irradiation ($\lambda > 480$ nm) for an O₂-saturated PhCN solution containing (TMP)Mn^{III}(OH) (1.0×10^{-5} M) in the presence of 5 (red), 10 (green), 20 (blue), or 30 mM (black) of AcrH₂ as a substrate at 298 K. (b) Plot of the initial reaction rate versus concentration of AcrH₂.

light intensity absorbed by **1** and also in the concentration of AcrH₂.

The initial reaction rate increased with increasing concentration of AcrH₂, as shown in Figure 2b. The initial reaction rates are proportional to the concentration of O₂ (Figure 3). Thus, the rate law is given by eq 4, where k_{ox} is the second-

$$\frac{d[\text{AcrH}_2]}{dt} = k_{\text{ox}}[S][\text{O}_2] \quad (4)$$

order rate constant and $[S]$ is the substrate concentration. The k_{ox} value was determined from the slope in Figure 2b to be $1.5 \times 10^{-5} \text{ M}^{-1} \text{ s}^{-1}$ for **1** and $8.5 \times 10^{-6} \text{ M}^{-1} \text{ s}^{-1}$ for **2** (Figures S3 in the SI).

The reaction solution of **1** (1.0×10^{-5} M) with O₂ and AcrH₂ ($0-1.5 \times 10^{-1}$ M) in O₂-saturated PhCN (2.0 mL) was irradiated to determine the quantum yield by changing the light source from a xenon lamp with a transmitting glass filter ($\lambda > 480$ nm) to nanosecond pulse where typical pulse energies at the sample were in the range of 10 mJ per pulse laser at 476 nm. The absorption band for Acr=O appeared, and the concentration of Acr=O increased linearly with excitation numbers. The zeroth-order rate constant of the photocatalytic

Figure 3. Plot of the initial reaction rate for the oxidation of (TMP)Mn^{III}(OH) (1.0×10^{-5} M) with O₂ ($0-8.5 \times 10^{-3}$ M)^{36,37} and AcrH₂ (2.0×10^{-2} M) under photoirradiation by a xenon lamp ($\lambda > 480$ nm) versus the concentration of O₂ in PhCN at room temperature (298 K).

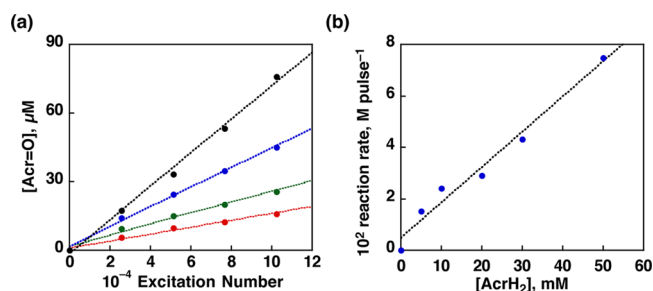

Figure 4. (a) Plots of the formation of Acr=O versus the laser excitation number for the photocatalytic oxygenation of AcrH₂ with an O₂-saturated PhCN solution containing (TMP)Mn^{III}(OH) (1.0×10^{-5} M) in the presence of 5.0 (red), 10 (green), 30 (blue), or 50 (black) of AcrH₂ as a substrate under irradiation by a nanosecond laser at 298 K. (b) Plot of the initial reaction rate versus concentration of AcrH₂.

oxidation of AcrH₂ by O₂ was also observed from the initial rate in Figure 4a. The quantum yield was determined to be 0.14% when **1** (1.0×10^{-5} M) with O₂ and AcrH₂ (1.5×10^{-1} M) in O₂-saturated PhCN (2.0 mL) was irradiated 1.0×10^5 times.

When AcrH₂ (0.20 M) was replaced by the deuterated compound, AcrD₂, the reaction rate of formation of Acr=O became significantly slower with 22 or 6 as the deuterium kinetic isotope effect (KIE) values for **1** or **2**, as shown in Figure 5. The KIE value shows that the hydrogen-atom transfer

Figure 5. Time courses of Acr=O formed under photoirradiation ($\lambda > 480$ nm) of an O₂-saturated PhCN solution (0.5 mL) containing (a) **1** or (b) **2** (1.7×10^{-4} M) and AcrH₂ (blue, 0.20 M) or AcrD₂ (red, 0.20 M).

(HAT) from AcrH₂ is directly involved in the rate-determining step for the photocatalytic reaction of (P)Mn^{III} with O₂ and AcrH₂.

Femtosecond Transient Absorption Measurements.

Femtosecond transient absorption spectroscopy was employed to investigate the photochemical processes involved in the photocatalytic oxygenation of AcrH_2 with $(\text{P})\text{Mn}^{\text{III}}$ and O_2 . Time-resolved transient absorption measurements by femtosecond laser flash photolysis of $(\text{P})\text{Mn}^{\text{III}}$ were performed in the absence and presence of O_2 in PhCN. Figure 6a shows the transient absorption spectral change of **1** in N_2 -saturated PhCN. Femtosecond laser excitation at 393 nm resulted in an instantaneous appearance of an absorption maximum at $\lambda_{\text{max}} = 638$ nm, which is assigned to the tripquintet excited state ($^5\text{T}_1$). It has been reported that the Mn^{III} metal ion has a d^4 ground-state electronic configuration ($S = 2$).^{29,38} Therefore, the (π, π^*) states of $(\text{P})\text{Mn}^{\text{III}}$ are not the normal singlets or triplets because of coupling of the unpaired metal electrons with the ring π electrons of the corrolazine ring. The ground state is a quintet ($^5\text{S}_0$), and a quintet excited state ($^5\text{S}_1$) is derived from the lowest excited ring (π, π^*) singlet.^{29,38} The excited states of first-row paramagnetic complexes, such as Mn^{III} complexes, undergo an extremely rapid intersystem crossing (ISC) process from the quintet ($^5\text{S}_1$) excited state to the tripquintet ($^5\text{T}_1$) excited state.^{38–42} The transient absorption spectra in Figure 6a show the decay of the absorption band at 638 nm, indicating ISC from the tripquintet ($^5\text{T}_1$) state to the long-lived tripseptet ($^7\text{T}_1$) state, which has an absorption band at 565 nm. From the

decay profile of the tripquintet ($^5\text{T}_1$), a rate constant of $2.3 \times 10^{10} \text{ s}^{-1}$ obeying first-order kinetics in degassed PhCN (Figure 6b) was determined. The rate constant of $2.5 \times 10^{10} \text{ s}^{-1}$ was also determined in aerated PhCN (Figure 6c), indicating no oxygen dependence on the rate of ISC.

The absorbance at 565 nm due to $^7\text{T}_1$ was diminished faster in O_2 -saturated PhCN (Figure 6e) rather than in deaerated PhCN (Figure 6d), providing a direct reaction between the excited state and O_2 . The second-order rate constant of the decay of $[(\text{TMP})\text{Mn}^{\text{III}}(\text{OH})]^* (^7\text{T}_1)$ in the presence of O_2 was determined to be $(8.1 \pm 2.0) \times 10^9 \text{ M}^{-1} \text{ s}^{-1}$, which is comparable to the diffusion-limited rate constant in PhCN ($5.6 \times 10^9 \text{ M}^{-1} \text{ s}^{-1}$).⁴³ The fast absorbance decay for $^7\text{T}_1$ also occurred when $(\text{P})\text{Mn}^{\text{III}}$ replaced from **1** to **2** (Figure S4 in the SI) with $2.0 \times 10^7 \text{ M}^{-1} \text{ s}^{-1}$ of the second-order rate constant of the decay of $[(\text{TPFPP})\text{Mn}^{\text{III}}(\text{CH}_3\text{COO})]^* (^7\text{T}_1)$. Together with the second-order rate constant of the decay of $[(\text{TBP}_8\text{Cz})\text{Mn}^{\text{III}}]^* (^7\text{T}_1)$, which is $4.9 \times 10^9 \text{ M}^{-1} \text{ s}^{-1}$,²⁹ the second-order rate constants of the decay of $[\text{Mn}^{\text{III}}]^* (^7\text{T}_1)$ corresponding to the rate constant of bimolecular reaction between $[\text{Mn}^{\text{III}}]^* (^7\text{T}_1)$ and O_2 increased in the order of $(\text{TMP})\text{Mn}^{\text{III}}(\text{OH})$, $(\text{TBP}_8\text{Cz})\text{Mn}^{\text{III}}$, and $(\text{TPFPP})\text{Mn}^{\text{III}}(\text{CH}_3\text{COO})$. This order agrees with the order of the maximum turnover number of photocatalytic oxidation of AcrH_2 in the presence of Mn^{III} in O_2 -saturated PhCN under photoirradiation.

Figure 6. (a) Transient absorption spectral changes (red after 10 ps, blue 50 ps, and black 3000 ps) after photoexcitation of $(\text{TMP})\text{Mn}^{\text{III}}(\text{OH})$ in PhCN. Decay time profiles of absorbance at 638 nm due to $[(\text{TMP})\text{Mn}^{\text{III}}(\text{OH})]^* (^5\text{T}_1)$ (b) in N_2 -saturated PhCN and (c) in O_2 -saturated PhCN. Decay time profiles of absorbance due to $[(\text{TMP})\text{Mn}^{\text{III}}(\text{OH})]^* (^7\text{T}_1)$ at $\lambda = 565$ nm under (d) N_2 and (e) O_2 .

Porphyrins and metalloporphyrins are well-known to be effective triplet-state photosensitizers and to be capable of producing singlet oxygen ($^1\text{O}_2^*$) due to direct energy transfer from the porphyrin excited triplet state to molecular oxygen. To examine a role for singlet oxygen in this photochemistry, the possibility of generation of $^1\text{O}_2^*$ has been examined by comparison of $^1\text{O}_2^*$ phosphorescence spectra in the presence of (P)Mn^{III} or C₆₀. The photoexcitation of (P)Mn^{III} with light of $\lambda = 532$ nm in O₂-saturated deuterated benzene (C₆D₆) results in a negligible phosphorescence signal at 1270 nm,⁴⁴ which is the phosphorescence spectrum of $^1\text{O}_2^*$, whereas that obtained by photoirradiation of C₆₀ under the same conditions shows significantly intense spectra, as shown in Figure S5 in the SI. Thus, it was assessed that the contribution of $^1\text{O}_2^*$ for the photochemical oxidation of (P)Mn^{III} with O₂ may be negligible as compared with an electron-transfer pathway from [(P)Mn^{III}]* ($^7\text{T}_1$) to O₂. It has been revealed that a significant role for $^1\text{O}_2^*$ was ruled out upon the photochemical oxidation of (TBP₈Cz)Mn^{III} to (TBP₈Cz)Mn^V(O) by use of a $^1\text{O}_2^*$ trap reagent, 9,10-dimethylanthracene.²⁹

Photocatalytic Mechanism. The mechanism of photocatalytic oxidation of AcrH₂ by O₂ with (P)Mn^{III} to give Acr=O as the product is proposed according to the photodynamics of (P)Mn^{III}, together with the large KIE values, as shown in Scheme 1. After photoexcitation of (P)Mn^{III}, the tripquintet

Scheme 1. Mechanism of Photocatalytic Oxidation of AcrH₂ in the Presence of (P)Mn^{III} and O₂

excited state ([(P)Mn^{III}]* ($^5\text{T}_1$)) is produced and converted rapidly to the triplet excited state ([(P)Mn^{III}]* ($^7\text{T}_1$)) by ISC. Generated [(P)Mn^{III}]* ($^7\text{T}_1$) undergoes electron transfer from [(P)Mn^{III}]* ($^7\text{T}_1$) to O₂ to produce the superoxo complex [(P)Mn^{IV}(O₂^{•-})], followed by HAT from O₂^{•-} moiety to the (P)Mn^{IV} to produce the hydroperoxo complex (P)Mn^{IV}(OOH) and acridinyl radical (AcrH[•]), which is the rate-determining step of the overall reaction. This reaction is most likely in competition with the back electron transfer from O₂^{•-} moiety to the (P)Mn^{IV} to regenerate the ground state of (P)Mn^{III} and O₂. The subsequent O–O bond cleavage by AcrH[•] may occur rapidly inside of the reaction cage before the reaction of AcrH[•] with O₂ to yield (P)Mn^V(O) and 9-hydroxy-10-methyl-9,10-dihydroacridine [AcrH(OH)]. This is followed by subsequent facile oxidation of AcrH(OH) by (P)Mn^V(O) to yield Acr=O, accompanied by regeneration of (P)Mn^{III} (Scheme 1).

When the hydrogen transfer from AcrH₂ to (P)Mn^{IV}(O₂^{•-}) is the rate-determining step in the catalytic cycle in Scheme 1,

the rate of formation of Acr=O is given by eq 5, where k_{H} is the rate of HAT from AcrH₂ to (P)Mn^{IV}(O₂^{•-}).

$$\frac{d[\text{Acr=O}]}{dt} = k_{\text{H}}[\text{AcrH}_2][(\text{P})\text{Mn}^{\text{IV}}(\text{O}_2^{\bullet-})] \quad (5)$$

The rate of formation and decay of (P)Mn^{IV}(O₂^{•-}) is given by eq 6

$$\begin{aligned} \frac{d[(\text{P})\text{Mn}^{\text{IV}}(\text{O}_2^{\bullet-})]}{dt} &= k_{\text{et}}[{}^7\text{T}_1][\text{O}_2] - k_{\text{H}}[\text{AcrH}_2][(\text{P})\text{Mn}^{\text{IV}}(\text{O}_2^{\bullet-})] \\ &\quad - k_{-\text{et}}[(\text{P})\text{Mn}^{\text{IV}}(\text{O}_2^{\bullet-})] \end{aligned} \quad (6)$$

where k_{et} is the rate constant of electron transfer from [(P)Mn^{III}]* ($^7\text{T}_1$) to O₂ to produce (P)Mn^{IV}(O₂^{•-}) and $k_{-\text{et}}$ is the back electron transfer from the O₂^{•-} moiety to the (P)Mn^{IV} moiety to regenerate (P)Mn^{III} and O₂. The rate of formation and decay of $^7\text{T}_1$ is given by eq 7

$$\frac{d[{}^7\text{T}_1]}{dt} = \Phi_0 I_{\text{a}} - k_{\text{et}}[{}^7\text{T}_1][\text{O}_2] - k_2[{}^7\text{T}_1] \quad (7)$$

where Φ_0 is the quantum yield of formation of $^7\text{T}_1$, I_{a} is the light intensity absorbed by 1, and k_2 is the decay rate constant of $^7\text{T}_1$ without O₂. By applying the steady-state approximation, the steady-state concentration of $^7\text{T}_1$ is derived from eq 7, as shown by eq 8

$$[{}^7\text{T}_1] = \frac{\Phi_0 I_{\text{a}}}{(k_{\text{et}}[\text{O}_2] + k_2)} \quad (8)$$

The steady-state concentration of Mn^{IV}(O₂^{•-}) is also derived from eqs 6 and 8, as given by eq 9

$$[(\text{P})\text{Mn}^{\text{IV}}(\text{O}_2^{\bullet-})] = \frac{\Phi_0 I_{\text{a}} k_{\text{et}} [\text{O}_2]}{[(k_{-\text{et}} + k_{\text{H}}[\text{AcrH}_2])(k_2 + k_{\text{et}}[\text{O}_2])]} \quad (9)$$

Then, the quantum yield for photocatalytic oxidation of AcrH₂ is derived from eqs 5 and 9, as given by eq 10

$$\Phi = \frac{\Phi_0 k_{\text{H}} k_{\text{et}} [\text{AcrH}_2] [\text{O}_2]}{[(k_{-\text{et}} + k_{\text{H}}[\text{AcrH}_2])(k_2 + k_{\text{et}}[\text{O}_2])]} \quad (10)$$

Equation 10 is rewritten by eq 11

$$\Phi^{-1} = \Phi_0^{-1} \left[\left(\frac{k_{\text{H}}}{k_{-\text{et}}} \right)^{-1} [\text{AcrH}_2]^{-1} + 1 \right] \left[\left(\frac{k_{\text{et}}}{k_2} \right)^{-1} [\text{O}_2]^{-1} + 1 \right] \quad (11)$$

where there are linear correlations for Φ^{-1} versus $[\text{AcrH}_2]^{-1}$ and Φ^{-1} versus $[\text{O}_2]^{-1}$. Linear plots of Φ^{-1} versus $[\text{AcrH}_2]^{-1}$ and Φ^{-1} versus $[\text{O}_2]^{-1}$ are shown in Figure 7a and b,

Figure 7. Linear plots of Φ^{-1} versus $[\text{AcrH}_2]^{-1}$ and Φ^{-1} versus $[\text{O}_2]^{-1}$.

respectively. From the slopes and intercepts of the linear plots, the $k_{\text{H}}/k_{\text{et}}$ and k_{et}/k_2 values were obtained as 53 and 7, respectively.

CONCLUSIONS

Photocatalytic oxidation of AcrH_2 by O_2 with $(\text{P})\text{Mn}^{\text{III}}$ (1 and 2) in PhCN occurs to produce $\text{Acr}=\text{O}$ as the sole oxidation product. The kinetic and laser flash photolysis measurements revealed the photocatalytic mechanism, as shown in Scheme 1, where electron transfer from the excited state $[(\text{P})\text{Mn}^{\text{III}}]^*$ ($^7\text{T}_1$) to O_2 occurs to produce the superoxo complex $[(\text{P})\text{Mn}^{\text{IV}}(\text{O}_2^{\bullet-})]$, which oxidizes AcrH_2 to $\text{Acr}=\text{O}$ via hydrogen-atom transfer from AcrH_2 to $[(\text{P})\text{Mn}^{\text{IV}}(\text{O}_2^{\bullet-})]$ and formation of $(\text{P})\text{Mn}^{\text{V}}(\text{O})$. The photocatalytic reactivity of $(\text{P})\text{Mn}^{\text{III}}$ agrees with the rate constants of electron transfer from $[(\text{P})\text{Mn}^{\text{III}}]^*$ ($^7\text{T}_1$) to O_2 in the order $(\text{TMP})\text{Mn}^{\text{III}}(\text{OH}) > (\text{TBP}_8\text{Cz})\text{Mn}^{\text{III}} > (\text{TPFP})\text{Mn}^{\text{III}}(\text{CH}_3\text{COO})$. The present study paves the way for development of new photocatalytic oxidation of substrates by O_2 using manganese porphyrins.
