Supporting Information

ABSTRACT: Two original macrocyclic silver(I)(pyridine-containing ligand) complexes [Ag(I)(Pc-L)] were synthesized and characterized. Their ability to catalyze the coupling among aldehydes, terminal alkynes and amines (A³-coupling) was demonstrated. The reaction could be performed under conventional as well as dielectric heating. The catalysts were effective in both cases, but dielectric heating allowed a lower catalyst loading and reduced ratio among reaction partners in shorter reaction times. The reaction scope was broad, including aryl/alkyl aldehydes, aryl/alkyl acetylenes and secondary aliphatic amines. Some unprecedented propargylamines have been prepared. The new catalytic system was also tested with more challenging coupling partners such as aniline and ketones.

INTRODUCTION

Multicomponent reactions (MCR's) enable the synthesis of complex molecules starting from more than two simple building blocks in a single operative step.¹ These strategies allow reducing the overall time required to obtain the desired product, beside a valuable solvents and energy saving, and the reduction of waste production. The advantages from the ecological and economic point of view are significant. In this context, the transition-metal catalyzed three-component reaction of an aldehyde, an amine and an alkyne, better known as A³-coupling,² represents a worthwhile approach to propargylamines, which are recurrent moieties in biologically active compounds and valuable intermediates for the synthesis of more complex nitrogen-containing molecules. Starting from the pioneering works of Dax³ and Dyatkin,⁴ the most popular procedures for A³-coupling are based on copper(I) catalysis.⁵ Moreover, the other coinage metals, silver⁶ and gold,⁷ gave valuable results⁸ too, and some other metals such as iron,⁹ indium,¹⁰ zinc,¹¹ nickel,¹² cobalt¹³ and mercury¹⁴ demonstrated their skill to catalyze this transformation. In particular, regarding silver based catalysts, it is worth noting that the

catalytic systems most frequently used are simple silver(I) salts (e.g., AgX,^{6,15} Ag₂O,¹⁶ or Ag₃PW₁₂O₄₀¹⁷) occasionally as acetonitrile complexes¹⁸ or (N-heterocyclic carbene)Ag(I) complexes.¹⁹ Interestingly, when this MCR was endeavored in the presence of phosphine-based Ag(I) complexes, a switch of activity was observed, and surprisingly the simple propargyl alcohol originated from aldehyde-alkyne coupling was obtained.²⁰ On the other hand, the asymmetric version of the A³-coupling (the so-called AA³-coupling) is absolutely dominated by Cu-based complexes,²¹ and to the best of our knowledge no examples have been already reported with any other transition metal.²²

In connection with our ongoing interest in the study of metal catalyzed domino²³ and multicomponent²⁴ processes involving alkynes, carbonyl compounds and ammonia/amines, we are pleased to report a microwave enhanced synthesis of propargylamines, catalyzed by well-defined Ag(I) complexes which are characterized by the presence of an original tetraaza-

macrocyclic ligand. Macrocyclic ligands display a series of peculiar properties, when compared with their noncyclic analogues, which render their coordination chemistry and the catalytic activity of their complexes an interesting field of inquiry. These includes kinetic (resistance to ligand exchange), thermodynamic (large formation constants), spectral (high ligand field strengths), and structural effects.²⁵ A few years ago, we introduced a new class of 12-membered macrocyclic ligands, called Pc-L (pyridine containing ligands), which can be synthesized in good yields, starting from commercially available reagents, even in enantiopure form. These macrocycles were first synthesized by the group of research of Stetter in 1981,²⁶ and some years later they have been rediscovered as ligands for the coordination of lanthanide ions in MRI contrasting agents.²⁷ By appropriate choice of the starting materials in the target macrocycle synthesis, we reasoned that the presence of a pyridine ring fused to the macrocycle could provide an enhanced conformational preorganization to the molecule, binding strongly to the metal atom while still allowing for the coordination of other molecules directly involved in the desired reaction. With the optimized reaction conditions, a small library of Pc-Ls has been obtained, including enantiomerically pure stereoisomers, and their copper and silver complexes demonstrated to be effective in catalysis. The cyclopropanation reaction of alkenes,²⁸ and the Henry reaction²⁹ were successfully catalyzed by some original copper based (Pc-L) complexes. Very recently, the addition/cycloisomerization reaction of 2-alkynylbenzaldehydes and alcohols under mild

reaction conditions was effectively promoted by some new $[Ag(I)(Pc-L)]^+X^-$ complexes.³⁰

RESULTS AND DISCUSSION

As mentioned above, we recently reported on the synthesis of some well-defined $[Ag(I)(Pc-L)]^+X^-$ complexes ($X = BF_4$, OTf, N(Tf)₂) characterized by the presence of a benzyl group on N6, capable to catalyze in good yield the one pot addition/cycloisomerization reaction of 2-alkynylbenzaldehydes and alcohols to yield 3-substituted-1-alkoxyisochromenes (Figure 1, A).³⁰ These silver complexes were quite stable, versatile and could be used without the need of a protective atmosphere, but they have the disposition to soak moisture from air to form monoquo species (Figure 1, B). We have already shown recently that the presence of a 1-(naphthyl)methyl substituent on the N6 of the macrocycle confers a good stability to the metal complexes of these Pc-Ls (i.e., copper(I) complexes),^{28b} by providing a further coordination site for the metal atom (Figure 1, C). This additional coordination site provided by the naphthyl group works as a "protecting cap" for the metal center, so avoiding the formation of undesirable pentacoordinated species with adventitious solvents or water. On the other hand, a suitable more electron-rich molecule in the reaction environment could easily displace the naphthyl cap (Figure 1, D).

For that reason in the present study we turned our attention to the use of the 1-(naphthyl)methyl substituted Pc-L, **1**, that can be obtained in good overall yield from commercially available starting materials according to Scheme 1.^{28b} The

synthetic strategy involved the nucleophilic ring opening of 1-tosylaziridine by naphthalen-1-ylmethanamine to give the corresponding 1,7-ditosyl-4-(naphthalen-1-ylmethyl)-1,4,7-triazheptane in quantitative yields. The approach has been improved by the use of dielectric heating, that not only allowed an overall increase of the yield in shortened reaction times, but moreover the product obtained was sufficiently pure to be used in the macrocyclization step, without need of further purification. Thus, the so obtained *bis*-protected triamine was directly reacted with 2,6-pyridinedimethanol 2,6-dimesylate in refluxing anhydrous acetonitrile in the presence of anhydrous K₂CO₃, to yield the macrocycle **1** in 76% yield.

The silver(I) complexes **2a,b** were synthesized in good yields by simple reaction in 1,2-dichloroethane of macrocyclic ligand with the proper silver salts.³⁰ In the step of formation of the complex, the silver salts and all silver containing solutions were kept in the dark and under protective atmosphere until the isolation of the final products. The silver complexes were collected as white powder from *n*-hexane and once isolated showed a remarkable stability in open air. They have been fully characterized by NMR, IR and UV–vis spectroscopies and electrospray ionization mass spectrometry (ESI-MS) analyses. As already observed for copper complexes,^{28b} also the new silver complexes **2a,b** displayed the η^2 coordination of the naphthyl substituent (Scheme 1) as established by ¹H and ¹³C NMR studies in CDCl₃ solution. In both ¹³C NMR spectra of complexes **2a,b** (that showed a very close signals pattern) a significant shift to lower frequencies of the carbon **a** involved in the η^2 bond with silver was observed, precisely from 125.1 ppm in the free ligand **1** to 112.3 and 112.4 ppm in the silver complexes **2a,b**, respectively (see Supporting Information). Moreover, in ¹³C NMR APT (attached-proton test) experiments, the signal around 112 ppm appeared broadened, probably due to the coupling with the silver atom. An opposite effect could be observed in the ¹H NMR, where the proton directly bound to carbon **a** experienced a higher frequencies shift (i.e., from 8.13 ppm in the free ligand **1**, to 9.16 and 9.18 in complexes **2a** and **2b**, respectively). A similar high frequency shift, although to a lesser extent, is observed also for the proton bound to carbon **b** (from 7.45 ppm in **1**, to 7.90 and 7.92,

respectively, in the metal complexes **2a,b**). The observed coupling constant ¹J_{C–H} of 157 Hz for carbon **a** in complex **2b** provided a hint of a partial rehybridization state from sp² to sp³. A ¹H–¹⁹F HOESY (heteronuclear Overhauser effect spectroscopy) spectrum of complex **2a** in deuterated chloroform showed that the tetrafluoroborate anion has weak proximity interactions only with the pyridine ring (see Supporting Information). A comparison between the UV spectra of the ligand **1** and of the metal complexes **2a,b** showed that the shape of the absorption bands did not change upon complexation, and only modest differences in the intensities were observed. The measured bands in the near UV were thus attributed to ligand-centered transitions and were consistent with the absence of color of the complexes **2a** and **2b**.

We started our study testing the [Ag(I)(Pc-L)]⁺ BF₄[–] complex **2a** on a model reaction involving simple and easily available starting materials, i.e., benzaldehyde **3a**, phenylacetylene **4a** and pyrrolidine **5a**. The results are reported in Table 1. In a first experiment, we tried the reaction in 0.5 mmol scale using the ratio among reagents, the temperature, and the catalyst loading more frequently reported in the literature for A³-couplings (i.e., ratio aldehyde/amine/alkyne = 1:1.5:1.5, T = 100 °C, cat. 3 mol %). Under these typical reaction conditions, we briefly explored the effect of some different solvents with decreasing relative polarity³¹ (Table 1, entries 1–5). We were pleased to find that complex **2a** was able to catalyze the reaction in all solvent tested. Higher yields were obtained performing the reaction in water, methanol and in toluene (Table 1, entries 1, 2 and 5). It is interesting to note that, despite the low solubility in water of the catalyst **2a** and reactants **3a**, **4a** and **5a**, the reaction however took place with fair yields (Table 1, entry 1), although at the end of the reaction a great amount of free metallic silver(0) was observed in the bottom of the test tube. A similar behavior was detected when the reaction was performed in methanol (Table 1, entry 2), whereas in toluene only traces of Ag(0) as silver mirror were observed on the internal surface of the test tube (Table 1, entry 5), so this solvent was chosen to optimize the conditions. The addition of a small amount of 3 Å molecular sieve did not strongly influence the reaction yields in both best solvents (i.e.,

methanol and toluene, Table 1, entries 6 and 7). Decreasing the temperature to rt caused the reaction to become extremely sluggish, and the yield was poor (Table 1, entry 8). Conversely, increasing the catalyst loading to 6 mol % caused an improvement in yield up to 87% to be observed (Table 1, entry 9). Moreover, changing the counterion of the complex from BF₄⁻ (2a) to the slightly more coordinating³² TfO⁻ (2b) an additional rise in yield was observed (Table 1, entry 10).

In spite of the remarkable results obtained, the approach suffers for the relatively long reaction times (4–5 h) and quite high catalyst loading (6 mol %). To improve the efficiency of the approach we decide to change the energy source. The ability of dielectric heating to promote different type of Cu(I) catalyzed A³-coupling has been well established and described by Leadbeater,³³ Tu³⁴ and Van der Eycken,³⁵ so we decide to proceed our study under microwave irradiation (Table 2). It is well-known that the efficiency of dielectric heating is strongly

related to the nature and the polarity of the solvent.³⁶ For this reason we repeated the solvent screening (Table 2, entries 1–6), and somewhat surprisingly, we found that also under microwave heating toluene demonstrated to be the best solvent (Table 2, entry 5); the reaction was complete in 15 min with excellent yield. Moreover, we found that the ratio among reaction partners could be advantageously reduced to 1:1.03:1.03 without loss of efficiency. Furthermore, we tried to reduce also the catalyst loading (Table 2, entries 7 and 8) and we found that 3 mol % of the catalyst was sufficient to obtain excellent results (Table 2, entry 7), whereas in the presence of 1 mol % of catalyst the yield dropped to 67% (Table 2, entry 8). Also the reaction time can be reduced to 10 min without appreciable loss of efficiency (Table 2, entry 9), whereas 5 min resulted in slightly lower yield (Table 2, entry 10). Finally, we performed two control experiments under the optimized reaction conditions in the presence of simple silver triflate as catalyst (Table 2, entries 11 and 12). Though the model reaction in the presence of 3 mol % of AgOTf gave the product **6a** in very good yield, the activity of complex **2b** appeared superior (Table 2, cf. entry 7 and 11), in particular when the catalyst loading was reduced to 1 mol % (Table 2, cf. entry 8 and 12), thus confirming a certain ligand effect. To be sure that also under this relatively harsh reaction conditions, the active catalytic species were actually the Ag[Pc-L] complexes and not degradation products or an in situ generated silver nanoparticles, we made two additional experiments. The complex **2a** was heated at 150 °C in toluene (complex **2a** is slightly soluble in toluene at rt, but dissolves at 150 °C) by dielectric heating for 10 min. Despite that at the end of the heating we observed a small amount of dark precipitate in the test tube, the ¹H NMR of the solution revealed that the silver(I) complex was still intact. Moreover, we performed the model reaction under conventional heating at 120 °C in the presence of a drop of mercury as np-inhibitor:³⁷ after 2 h, we obtain the desired propargylamine **6a** in 36% yield.

With the best conditions in hand, we explored scope and limitation of the reaction. In particular, our target was to verify the ability of our catalysts to promote the reaction among

partners of different nature, such as substituted aliphatic and aromatic aldehydes, alkynes substituted with alkyl or aryl moieties, and secondary amines. The results are reported in Table 3. EWGs and EDGs on arylalkyne partner were in general well-tolerated (Table 3, entries 2, 3, 11–13), except for strongest EWG such as nitro group (Table 3, entry 4). Benzaldehyde derivatives bearing EWGs or EDGs in any position of the ring gave satisfying results (Table 3, entries 6–8) as well as cyclohexanecarbaldehyde (Table 3, entries 9 and 11). Nevertheless, also in this case lower yields were obtained when the aldehyde was characterized by an acyclic alkyl substitution (Table 3, entry 10). The nature of the amine seemed to be the more critical feature. Cyclic secondary amines such as pyrrolidine and piperidine gave best results (Table 3, entries 1–3, 6–9, 11–13), whereas acyclic secondary amines (Table 3, entries 15, 16) and less basic cyclic amines as morpholine (Table 3, entry 14) gave only fair to good reaction yields.

It is well-known that the A³-coupling process was mainly optimized with aliphatic secondary amines for the synthesis of tertiary propargylamines. Considerable work has been done also with anilines for the synthesis of secondary *N*-arylpropargylamines, but it is difficult to find a single catalytic system capable to efficiently catalyze both the transformations.³⁴ Moreover, primary alkyl amines as well as ketones were generally considered to be very difficult substrates. With the aim to broaden the scope of our approach, we tested our [Ag(I)(Pc-L)] catalysts with some of these more challenging substrates, in particular aromatic amines and ketones. A number of examples of A³-coupling reactions with anilines as amine partners have been reported in the literature, mainly catalyzed by Cu(I) salts and complexes,^{21d,e,39} or else Ru(III)–Cu(I),⁴⁰ AuCl₃–CuBr,⁴¹ and InBr₃,^{10b} but only a single reaction catalyzed by a simple silver catalyst (silver iodide) was published.⁴² On the other side, in the literature are reported some examples of that variant of A³-coupling, called KA²-coupling, that involves the use of a ketone instead of an aldehyde to yield propargylamines bearing a quaternary carbon. In most cases these reactions were performed with copper(I/

II)⁴³ salts as catalysts, but also isolated examples catalyzed by gold(III)⁴⁴ and Ti(IV)/Cu(II)⁴⁵ salts were reported. However, to the best of our knowledge, no examples of Ag catalyzed KA²-coupling have been already reported.

The results of our exploratory study with more challenging substrates are summarized in Table 4. The first attempt was performed with benzaldehyde **3a**, phenylacetylene **4a** and aniline **5f**. The reaction conditions were slightly modified: the catalyst loading and the reaction time were increased to 6 mol % and 20 min, respectively (Table 4, entry 1). Under these conditions, the corresponding propargylamine **6p** was obtained in a modest 28% yield, beside a 68% yield of the imine **7**. Also in this case, the addition of molecular sieve did not improve the yield of the desired product (Table 4, entry 2). Slightly better results were obtained by increasing the amount of alkyne **4a**, but also in these cases the imine **7** remained the main product (Table 4, entries 3 and 4). Conversely, the use of a 3-fold excess of amine and aldehyde partners was unsuccessful (Table 4, entry 5). On the basis of these results we argued that the low yields obtained were not related to the imine formation stage, but probably to a more difficult addition of the activated alkyne on the less electrophilic carbon of the imine intermediate. With the aim to obtain a more reactive aryl-iminium intermediate we tested the reaction with diphenylamine **5g**, as secondary arylamine,^{5a} but in these cases the reactions totally failed (Table 4, entries 6 and 7), and complex mixtures of unidentified products were obtained.

Concerning the KA²-coupling, we briefly tested the reactivity of 2-pentanone **8a**, phenylacetylene **4a** and pyrrolidine **5a** in the reaction conditions adopted for the A³-couplings with aniline (i.e., toluene, 6 mol % of catalyst, microwave heating, 150 °C, 20 min), and different molar ratio between reactants were tested (Table 4, entries 8–10). With the aim to facilitate the formation of the keto-iminium cation, 4 Å molecular sieves were added to the reaction mixture. Unfortunately, also in these cases the reaction yields were unsatisfactory. Probably, the reaction is low yielding due to the intrinsic lower reactivity of ketones more hindered and less electrophilic than aldehydes. This hypothesis was also supported by the complete failure of the reaction with the less reactive acetophenone **8b** and benzophenone **8c** (Table 4, entries 11 and 12).

¹H NMR experiments in CDCl₃ at room temperature showed no interaction between the metal complexes and the aldehyde, while a remarkable shift, especially for the signals originally involved in the η^2 coordination of the naphthyl moiety to the silver atom were observed upon addition of both the phenylacetylene **4a** or pyrrolidine **5a**. In the absence of any base, however, complex **2a** reacts very easily with a terminal alkyne to give the silver acetylide. This liberates acid, which protonates the ligand causing partial decomplexation. This decomplexation does not happen in the presence of a stoichiometric amount of pyrrolidine. On the basis of the experimental results and taking in mind the literature findings,^{6,19c} a tentative mechanism was proposed: first the catalyst form the π -complex (**I**) with the alkyne **4** (an equilibrium with the silver complex coordinated to the amine cannot be however ruled out). This increase the acidity of acetylenic hydrogen which is removed by the amine (or more probably by the emiaminal intermediate resulted from the reaction between the amine **5** and the aldehyde **3**) to give silver acetylide **II**. The proton assisted condensation between the amine **5** and the aldehyde **3** generate a molecule of water and the iminium halide **III**, which reacts with the silver acetylide **II**

to afford the desired propargylamine **6** and regenerate the catalyst (Scheme 2).

Scheme 2. Tentative Mechanism Proposed

CONCLUSIONS

In conclusion, we have synthesized and in depth characterized two original Ag(I)(Pc-L) complexes and their catalytic activity was tested in A³-coupling MCR. We optimized the reaction conditions both under conventional and microwave heating. The catalysts were effective in both cases, but dielectric heating allowed a lower catalyst loading and a reduced ratio among reaction partners in shorter reaction times. The reaction scope was broad when secondary aliphatic amines were used, and some unprecedented propargylamines have been prepared. This work represents the first example of A³-coupling catalyzed by tetraaza-macrocyclic silver complexes. Moreover, some explorative experiments demonstrated that the new catalysts worked with more challenging reaction partners such as aromatic amines and ketones too, although the results, in these cases, are only modest. Current efforts are now devoting to design and synthesize some new chiral [Pc-L]* ligands characterized by a well-planned chiral profile able to induce stereoselectivity in this valuable MCR.

EXPERIMENTAL SECTION

General Experimental Details. All of the reactions that involved the use of reagents sensitive to oxygen or hydrolysis were carried out under an inert atmosphere. The glassware was previously dried in an oven at 110 °C and was set with cycles of vacuum and nitrogen. Also syringes, used to transfer reagents and solvents, were previously set under a nitrogen atmosphere. The syntheses of the silver complexes were carried out under a nitrogen atmosphere by employing standard Schlenk techniques. All chemicals and solvents were commercially available and were used after distillation or treatment with drying agents. The chromatographic column separations were performed by a flash technique, using silica gel (pore size 60 Å, particle size 230–400 mesh, Merck grade 9385). For TLC, silica was used on TLC Alu foils with fluorescent indicator (254 nm) and the detection was performed by irradiation with UV light (λ = 254 or 366 nm). ¹H NMR analyses were performed with 200, 300, or 400 MHz spectrometers at room temperature. The coupling constants (*J*) are expressed in hertz (Hz), and the chemical shifts (δ) in ppm. ¹³C NMR analyses were performed with the same instruments at 50.3, 75.5, and 100 MHz, and attached

proton test (APT) sequence was used to distinguish the methine and methyl carbon signals from those arising from methylene and quaternary carbon atoms. All ^{13}C NMR spectra were recorded with complete proton decoupling. The ^1H NMR signals of the ligand described in the following have been attributed by correlation spectroscopy (COSY) and nuclear Overhauser effect spectroscopy (NOESY) techniques. Assignments of the resonance in ^{13}C NMR were made using the APT pulse sequence and heteronuclear single quantum correlation (HSQC) and heteronuclear multiple bond correlation (HMBC) techniques. The ^{15}N NMR signals of the compound described have been attributed by HMBC technique. Low resolution MS spectra were recorded with instruments equipped with electron ionization (EI), ESI/ion trap (using a syringe pump device to directly inject sample solutions), or fast atom bombardment (FAB) (for Pc-L and metal complexes) sources. The values are expressed as mass-charge ratio and the relative intensities of the most significant peaks are shown in brackets. High resolution MS spectra were recorded with an instrument equipped with an electrospray source and a ion cyclotron resonance-Fourier transform mass spectroscopy (ICR-FTMS) analyzer. UV-vis spectra of the ligand and its silver complexes were recorded in CHCl_3 . The melting points of the solid products are uncorrected. Microwave promoted reactions were performed with a single-mode Personal Chemistry microwave synthesizer "Emrys Creator", using sealed glass vessels. The temperature was detected with an infrared sensor.

Synthesis of 1,7-Ditosyl-4-(naphthalen-1-ylmethyl)-1,4,7-triazaheptane. A solution of tosyl aziridine (0.769 g, 3.90 mmol) and 1-naphthylmethylamine (0.283 g, 1.80 mmol) in MeOH (15 mL) was stirred and heated by microwave irradiation for 1 h at 120 °C. The mixture was dried and used without any further purification: yield quantitative (0.993 g, 1.80 mmol); ^1H NMR (300 MHz, CDCl_3 , δ) 8.14 (d, J = 8.3 Hz, 1H, H_{ar}), 7.86 (d, J = 8.3 Hz, 1H, H_{ar}), 7.78 (m, 1H, H_{ar}), 7.54 (d, J = 8.0 Hz, 4H, H_{ar}) overlapping with 7.61–7.49 (m, 2H, H_{ar}), 7.42–7.32 (m, 2H, H_{ar}), 7.19 (d, J = 8.0 Hz, 4H, H_{ar}), 4.83 (bs, 2H, NH), 4.00 (s, 2H, CH_2), 2.90 (m, 4H, CH_2), 2.66 (m, 4H, CH_2), 2.38 (s, 6H, CH_3). The spectral data are consistent with those previously reported.^{28b}

Synthesis of 6-(Naphthalen-1-ylmethyl)-3,9-ditosyl-3,6,9,15-tetraazabicyclo[9.3.1]pentadeca-1(15),11,13-triene 1. A solution of 1,7-ditosyl-4-(naphthalen-1-ylmethyl)-1,4,7-triazaheptane (2.053 g, 3.731 mmol), 2,6-bis(methanesulfonyloxymethyl)pyridine (1.101 g, 3.731 mmol) and micronized anhydrous potassium carbonate (1.547 g, 11.19 mmol) in freshly distilled acetonitrile (110 mL) was stirred and heated under reflux for 16 h. The mixture was washed with water (150 mL) and extracted with ethyl acetate (3 \times 80 mL). The organic layers were dried with sodium sulfate and then evaporated to dryness under reduced pressure. The crude product was then dissolved in hot ethyl acetate (60 mL), filtered while hot and layered with *n*-hexane (35 mL). After cooling at 0 °C an amorphous yellowish solid fell out from the solution. The solid was filtered off, and the mother liquors were evaporated to dryness, yielding a white solid: yield 1.857 g, 76%; ^1H NMR (400 MHz, CDCl_3 , δ) 8.14 (d, J = 8.1 Hz, 1H, H^i), 7.91 (d, J = 7.8 Hz, 1H, H^d o H^f), 7.87 (d, J = 8.1 Hz, 1H, H^d o H^f), 7.78 (t, J = 7.8 Hz, 1H, H^i), 7.50 (d, J = 8.2 Hz, 4H, H^b) overlapping with 7.51–7.45 (m, 3H, H_{ar}), 7.39 (d, J = 7.8 Hz, 2H, H^a), 7.35 (d, J = 6.9 Hz, 1H, H^b), 7.19 (d, J = 8.2 Hz, 4H, H^o), 4.31 (s, 4H, CH_2^2 and CH_2^{10}), 3.93 (s, 2H, CH_2^{13}), 3.07 (m, 4H, CH_2^4 and CH_2^8), 2.40 (s, 6H, CH_3^{14}), overlapping with 2.36 (m, 4H, CH_2^5 and CH_2^7); ^{13}C NMR (100 MHz, CDCl_3 , δ) 155.3 (C^1), 143.7 (C^p), 139.2 (C^{H}), 136.2 (C^m), 134.9 (C), 134.3 (C), 132.8 (C), 130.1 (C^{H}), 128.8 (C^{ArH}), 128.5 (C^{ArH}), 127.7 (C^{ArH}), 127.4 (C^{H}), 126.04 (C^{ArH}), 125.98 (C^{ArH}), 125.7 (C^{ArH}), 125.1 (C^{H}), 124.4 (C^{H}), 58.5 (C^{13}H_2), 54.7 (C^2H_2), 50.9 (C^5H_2), 44.7 (C^4H_2), 21.9 (C^{14}H_3); ^{15}N NMR (40 MHz; CDCl_3 , δ) 312 (N^{12}), 95 (N-Ts), 32 (N^6); MS (FAB) m/z (%) = 655 (100) [MH^+], 499 (34) [MH-Ts^+]; UV-vis (5.2×10^{-5} mol L^{-1} , CHCl_3 in 1 cm cuvettes); λ_{max} [nm] = 242, 264, 283, 296 nm.

General Procedure for the Synthesis of Silver Complexes 2a,b. The silver salt and all silver-containing solutions were kept in the dark until the final isolation of the product. The ligand 1 was dissolved in 1,2-dichloroethane, the silver salt (weighed under a nitrogen

atmosphere) was added, and the mixture stirred for 1 h, then filtered to remove any unreacted solid. The solvent was evaporated to dryness, then *n*-hexane was added, and the product recovered by filtration in open air.

2a. 1 (MW = 654.84; 0.137 g; 0.209 mmol), AgBF_4 (MW = 194.67; 0.041 g; 0.21 mmol), $\text{C}_2\text{H}_4\text{Cl}_2$ (10 mL), *n*-hexane (20 mL): yield 0.161 g (MW = 849.51) 90%; ^1H NMR (300 MHz, CDCl_3 , δ) 9.16 (d, J = 8.1 Hz, 1H, H^i), 8.12 (d, J = 8.1 Hz, 1H, H^f), 7.99 (d, J = 8.1 Hz, 1H, H^d), 7.90 (m, 1H, H^b), 7.81 (t, J = 7.9 Hz, 1H, H^i), 7.72 (m, 1H, H^b), 7.67–7.59 (m, 2H, H^c and H^e) overlapping with 7.59 (d, J = 7.8 Hz, 4H, H^n), 7.41 (d, J = 7.8 Hz, 4H, H^o), 7.24 (d, J = 7.9 Hz, 2H, H^a), 4.89 (d, J = 15.0 Hz, 2H, CH_2^2 and CH_2^{10}), 4.35 (br s, 2H, CH_2^{13}), 3.50 (d, J = 15.0 Hz, 2H, CH_2^4 and $\text{CH}_2^{10'}$) overlapping with 3.51–3.48 (m, 2H, CH_2), 2.81 (m, 2H, CH_2), 2.59 (m, 2H, CH_2), 2.49 (s, 6H, CH_3^{14}), 2.13 (m, 2H, CH_2). ^{13}C NMR (75 MHz, CDCl_3 , δ) 154.0 (C^1), 146.0 (C^p), 141.0 (C^{H}), 135.3 (C^m), 133.8 (C), 133.2 (C), 132.5 (C^{H}), 131.1 (C), 130.8 (C^{H}), 130.7 (C^{bH}), 130.0 (C^{dH}), 128.6 (C^{H}), 127.1 (C^{bH}), 126.4 (C^{ArH}), 125.8 (C^{ArH}), 125.3 (C^{H}), 112.3 (C^{H}), 56.4 (C^{13}H_2), 56.3 (C^2H_2 and C^{10}H_2), 54.7 (CH_2), 48.3 (CH_2), 22.1 (C^{14}H_3); ^{19}F NMR (282 MHz, CDCl_3 , δ) –152.8; MS (FAB) m/z (%) = 761/763 (90/100) [$\text{M} - \text{BF}_4$] $^+$, 655 (37) [$\text{MH} - \text{AgBF}_4$] $^+$; UV-vis (5.2×10^{-5} mol L^{-1} , CHCl_3 in 1 cm cuvettes); λ_{max} [nm] = 242, 264, 284, 295 nm. Anal. Calcd for $\text{C}_{36}\text{H}_{38}\text{AgBF}_4\text{N}_4\text{O}_4\text{S}_2$: C, 50.90; H, 4.51; N, 6.60. Found: C, 50.75; H, 4.61; N, 6.43.

2b. 1 (MW = 654.84; 0.867 g; 1.32 mmol), AgOTf (MW = 256.94; 0.340 g; 1.32 mmol), $\text{C}_2\text{H}_4\text{Cl}_2$ (26 mL); *n*-hexane (15 mL): yield 1.077 g (MW = 911.78) 89%; ^1H NMR (300 MHz, CDCl_3 , δ) 9.18 (d, J = 8.4 Hz, 1H, H^i), 8.12 (d, J = 8.4 Hz, 1H, H^f), 8.00 (d, J = 8.1 Hz, 1H, H^d), 7.92 (m, 1H, H^b), 7.84 (t, J = 7.7 Hz, 1H, H^i), 7.73 (m, 1H, H^b), 7.69–7.62 (m, 2H, H^c and H^e), 7.59 (d, J = 8.2 Hz, 4H, H^n), 7.41 (d, J = 8.2 Hz, 4H, H^o), 7.26 (d, J = 7.7 Hz, 2H, H^a), 4.88 (d, J = 15.0 Hz, 2H, CH_2^2 and CH_2^{10}), 4.36 (br s, 2H, CH_2^{13}), 3.59 (d, J = 15.0 Hz, 2H, CH_2^4 and $\text{CH}_2^{10'}$) overlapping with 3.57–3.49 (m, 2H, CH_2), 2.84 (m, 2H, CH_2), 2.74 (m, 2H, CH_2), 2.50 (s, 6H, CH_3^{14}), 2.26 (m, 2H, CH_2); ^{13}C NMR (75 MHz, CDCl_3 , δ) 154.1 (C^1), 146.0 (C^p), 141.0 (C^{H}), 135.3 (C^m), 133.7 (C), 133.2 (C), 132.7 (C^{H}), 131.2 (C), 130.8 (C^{H}) overlapping with 130.8 (C^{bH}), 130.1 (C^{dH}), 128.6 (C^{H}), 127.1 (C^{bH}), 126.5 (C^{ArH}), 125.9 (C^{ArH}), 125.4 (C^{H}), 112.4 (C^{H} , J $^1\text{H}-^{13}\text{C}$ = 156.8 Hz), 56.6 (C^{13}H_2), 56.4 (C^2H_2 and C^{10}H_2), 54.8 (CH_2), 48.3 (CH_2), 22.1 (C^{14}H_3); ^{19}F NMR (282 MHz, CDCl_3): δ = –78.5; MS (FAB) m/z (%) = 761/763 (90/100) [$\text{M} - \text{CF}_3\text{SO}_3$] $^+$, 655 (35) [$\text{MH} - \text{AgCF}_3\text{SO}_3$] $^+$. General Procedure for the A³-Coupling under Conventional Heating. The reactions were performed in a 0.5 mmol scale in open air. The catalyst (2a or 2b, 0.03 mmol) was dissolved in dry toluene (1 mL) in a screw-cap test tube equipped with a stirring bar. The suitable aldehyde (0.5 mmol), amine (0.75 mmol) and alkyne (0.75 mmol) were added to the stirred solution, according to this order. The mixture was stirred and heated with an oil-bath at 100 °C (for reaction times see Table 1). The reaction mixture was diluted with ethyl acetate (20 mL), and the organic layer was washed with water (20 mL) and brine (20 mL). The organic layer was dried over sodium sulfate, and the solvent was evaporated under reduced pressure. The reaction crude was purified by flash column chromatography over a silica gel

column with gradients of *n*-hexane/ethyl acetate as eluent. For reaction yields see Table 1.

General Procedure for the A³-Coupling under Dielectric Heating. The reactions were performed in a 0.5 mmol scale in open air. The catalyst (**2a** or **2b**, 0.015 mmol) was dissolved in dry toluene (1 mL) in a sealed microwave vial equipped with a stirring bar. The suitable aldehyde (0.5 mmol), amine (0.515 mmol) and alkyne (0.515 mmol) were added to the stirred solution, according to this order. The mixture was heated in a single-mode microwave oven at 150 °C for 15 min. The reaction mixture was diluted with ethyl acetate (20 mL), and the organic layer was washed with water (20 mL) and brine (20 mL). The organic layer was dried over sodium sulfate, and the solvent was evaporated under reduced pressure. The reaction crude was purified by flash column chromatography over a silica gel column with gradients of *n*-hexane/ethyl acetate as eluent. (When the reaction yields were calculated by ¹H NMR with the internal standard, a precise amount of DMT (around 45 mg) was added to the reaction crude before the workup, and the ¹H NMR was recorded with a prolonged delay time (d1 = 10)).

1-(1,3-Diphenylprop-2-yn-1-yl)pyrrolidine 6a.^{7d} Pale yellow oil: yield 96% (125 mg); ¹H NMR (200 MHz, CDCl₃, δ) 7.61 (dd, *J* = 7.8, 1.7 Hz, 2H, H_{ar}), 7.53–7.44 (m, 2H, H_{ar}), 7.42–7.27 (m, 6H, H_{ar}), 4.89 (s, 1H, CH), 2.69 (pt, *J* = 6.7 Hz, 4H, N–CH₂), 1.98–1.61 (m, 4H, CH₂). Spectral data are in good agreement with literature values.

1-(3-(4-Methoxyphenyl)-1-phenylprop-2-yn-1-yl)pyrrolidine 6b. Pale yellow oil: yield 75% (109 mg); ¹H NMR (200 MHz, CDCl₃, δ) 7.60 (dd, *J* = 7.8, 1.2 Hz, 2H, H_{ar}), 7.42 (d, *J* = 8.9 Hz, 2H, H_{ar}), 7.37–7.27 (m, 3H, H_{ar}), 6.84 (d, *J* = 8.9 Hz, 2H, H_{ar}), 4.86 (s, 1H, CH), 3.81 (s, 3H, O–CH₃), 2.68 (pt, *J* = 6.6 Hz, 4H, N–CH₂), 1.83–1.75 (m, 4H, CH₂); ¹³C NMR (50.3 MHz, CDCl₃, δ) 159.7 (C_q), 139.9 (C_q), 133.4 (CH_{ar}), 128.54 (CH_{ar}), 128.46 (CH_{ar}), 127.8 (CH_{ar}), 115.6 (C_q), 114.2 (CH_{ar}), 87.0 (C_{sp}), 85.3 (C_{sp}), 59.4 (CH), 55.5 (O–CH₃), 50.5 (N–CH₂), 23.8 (CH₂); MS ESI(+) *m/z* (%) = 292.1 (4) [M + H]⁺, 221.2 (100) [M – pyrrolidine]⁺. HRMS ESI (M + H)⁺ calcd for C₂₀H₂₂NO⁺, 292.1696; found, 292.1701.

1-(3-(3-Fluorophenyl)-1-phenylprop-2-yn-1-yl)pyrrolidine 6c. Pale yellow oil: yield 83% (116 mg); ¹H NMR (200 MHz, CDCl₃, δ) 7.67–7.53 (m, 2H, H_{ar}), 7.44–7.23 (m, 6H), 7.23–7.13 (m, 1H), 7.11–6.90 (m, 1H), 4.91 (s, 1H, CH), 2.71 (pt, *J* = 6.6 Hz, 4H, N–CH₂), 1.88–1.76 (m, 4H, CH₂); ¹³C NMR (50.3 MHz, CDCl₃, δ) 162.6 (d, ¹*J*_{C–F} = 246.4 Hz, C_q), 139.3 (C_q), 130.0 (d, ³*J*_{C–F} = 8.7 Hz, CH_{ar}), 128.54 (CH_{ar}), 128.47 (CH_{ar}), 127.92 (CH_{ar}), 127.89 (d, ⁴*J*_{C–F} = 3.2 Hz, CH_{ar}), 125.3 (d, ³*J*_{C–F} = 9.5 Hz, C_q), 118.8 (d, ²*J*_{C–F} = 22.7 Hz, CH_{ar}), 115.7 (d, ²*J*_{C–F} = 21.2 Hz, CH_{ar}), 88.5 (C_{sp}), 86.0 (d, ⁴*J*_{C–F} = 3.3 Hz, C_{sp}), 59.3 (CH), 50.5 (N–CH₂), 23.7 (CH₂); MS ESI(+) *m/z* (%) = 280.2 (100) [M + H]⁺, 209.4 (48) [M – pyrrolidine]⁺. HRMS ESI (M + H)⁺ calcd for C₁₉H₁₉FN⁺, 280.1496; found, 280.1493.

1-(1-Phenylhex-2-yn-1-yl)pyrrolidine 6d. Pale yellow oil: yield 53% (60 mg); ¹H NMR (200 MHz, CDCl₃, δ) 7.53 (dd, *J* = 7.5, 1.5 Hz, 2H, H_{ar}), 7.44–7.19 (m, 3H, H_{ar}), 4.60 (t, *J* = 2.0, 1H, CH), 2.59 (pt, *J* = 6.2 Hz, 4H, N–CH₂), 2.26 (dt, *J* = 7.1, 2.0 Hz, 2H, CH₂), 1.79–1.73 (m, 4H, CH₂), 1.58 (ses, *J* = 7.1 Hz, 2H, CH₂), 1.02 (t, *J* = 7.2 Hz, 3H, CH₃); ¹³C NMR (50.3 MHz, CDCl₃, δ) 140.3 (C_q), 128.5 (CH_{ar}), 127.6 (CH_{ar}), 87.2 (C_{sp}), 77.3 (C_{sp}), 59.0 (CH), 50.4 (N–CH₂), 23.7 (CH₂), 22.7 (CH₂), 21.0 (CH₂), 13.8 (CH₃); MS ESI(+) *m/z* (%) = 228.1 (100) [M + H]⁺. HRMS ESI (M + H)⁺ calcd for C₁₆H₂₂N⁺, 228.1747; found, 228.1750.

1-(1-(4-Methoxyphenyl)-3-phenylprop-2-yn-1-yl)pyrrolidine 6e.⁴⁶ Pale yellow oil: yield 78% (114 mg); ¹H NMR (200 MHz, CDCl₃, δ) 7.46–7.54 (m, 4H, H_{ar}), 7.29–7.32 (m, 3H, H_{ar}), 6.89 (d, *J* = 8.6 Hz, 2H), 6.84 (d, *J* = 8.9 Hz, 1H, H_{ar}), 4.82 (s, 1H, CH), 3.81 (s, 3H, CH₃), 2.71–2.64 (m, 4H, N–CH₂), 1.82–1.76 (m, 4H, CH₂). Spectral data are in good agreement with literature values.

1-(1-(3-Chlorophenyl)-3-phenylprop-2-yn-1-yl)pyrrolidine 6f.⁴⁷ Pale yellow oil: yield 79% (117 mg); ¹H NMR (200 MHz, CDCl₃, δ) 7.63 (s, 1H, H_{ar}), 7.58–7.41 (m, 3H), 7.40–7.20 (m, 5H), 4.91 (s, 1H, CH), 2.84–2.60 (m, 4H, N–CH₂), 1.96–1.67 (m, 4H, CH₂); ¹³C NMR (50.3 MHz, CDCl₃, δ) 141.9 (C_q), 134.4 (C_q), 132.0 (CH_{ar}), 129.7 (CH_{ar}), 128.6 (CH_{ar}), 128.5 (CH_{ar}), 128.5 (CH_{ar}), 128.0 (CH_{ar}), 126.6 (CH_{ar}), 123.2 (C_q), 87.7 (C_{sp}), 85.9 (C_{sp}), 58.7 (CH),

50.3 (N–CH₂), 23.79 (CH₂); MS ESI(+) *m/z* (%) = 298.1/296.1 (30/100) [M + H]⁺. Spectral data are in good agreement with literature values.

2-(3-Phenyl-1-(pyrrolidin-1-yl)prop-2-yn-1-yl)phenol 6g.⁴⁸ Pale yellow oil: yield 83% (115 mg); ¹H NMR (200 MHz, CDCl₃, δ) 7.57–7.50 (m, 3H, H_{ar}), 7.41–7.32 (m, 3H, H_{ar}), 7.29–7.17 (m, 1H, H_{ar}), 6.95–6.79 (m, 2H, H_{ar}), 5.29 (s, 1H, CH), 2.96–2.75 (m, 4H, N–CH₂), 1.96–1.82 (m, 4H, CH₂). Spectral data are in good agreement with literature values.

1-(1-Cyclohexyl-3-phenylprop-2-yn-1-yl)pyrrolidine 6h.⁶ Colorless oil: yield 98% (131 mg); ¹H NMR (200 MHz, CDCl₃, δ) 7.48–7.38 (m, 2H, H_{ar}), 7.35–7.22 (m, 3H, H_{ar}), 3.36 (d, *J* = 8.4 Hz, 1H, CH), 2.80–2.60 (m, 4H, N–CH₂), 2.12–1.92 (m, 2H, C_{sp}3H), 1.85–1.52 (m, 8H, C_{sp}3H), 1.30–1.05 (m, 5H, CH₂); ¹³C NMR (50.3 MHz, CDCl₃, δ) 131.9 (CH_{ar}), 128.4 (CH_{ar}), 127.9 (CH_{ar}), 123.9 (C_q), 88.1 (C_{sp}), 86.0 (C_{sp}), 61.5 (CH), 50.3 (N–CH₂), 41.6 (CH), 30.9 (CH₂), 30.5 (CH₂), 26.9 (CH₂), 26.5 (CH₂), 23.8 (CH₂); MS ESI(+) *m/z* (%) = 268.2 (100) [M + H]⁺. Spectral data are in good agreement with literature values.

1-(1-Phenylhept-1-yn-3-yl)pyrrolidine 6i.⁶ Colorless oil: yield 61% (74 mg); ¹H NMR (200 MHz, CDCl₃, δ) 7.45–7.40 (m, 2H), 7.31–7.26 (m, 3H, H_{ar}), 3.67 (dd, *J* = 7.9, 6.7 Hz, 1H, CH, H_{ar}), 2.78–2.67 (m, 4H, N–CH₂), 1.84–1.26 (m, 10H, CH₂), 0.93 (t, *J* = 7.0 Hz, 3H, CH₃); ¹³C NMR (50.3 MHz, CDCl₃, δ) 131.9 (CH_{ar}), 128.4 (CH_{ar}), 127.9 (CH_{ar}), 123.8 (C_q), 88.7 (C_{sp}), 85.4 (C_{sp}), 55.4 (CH), 49.9 (N–CH₂), 35.1 (CH₂), 30.9 (CH₂), 29.1 (CH₂), 23.7 (CH₂), 22.7 (CH₂), 14.2 (CH₃); MS ESI(+) *m/z* (%) = 242.1 (100) [M + H]⁺, 171.2 (12) [M – pyrrolidine]⁺. Spectral data are in good agreement with literature values.

1-(1-Cyclohexyl-3-(4-methoxyphenyl)prop-2-yn-1-yl)pyrrolidine 6j. Colorless oil: yield 89% (132 mg); ¹H NMR (200 MHz, CDCl₃, δ) 7.36 (d, *J* = 8.9 Hz, 2H, H_{ar}), 6.82 (d, *J* = 8.9 Hz, 2H, H_{ar}), 3.80 (s, 1H, O–CH₃), 3.32 (d, *J* = 8.3 Hz, 1H, CH), 2.77–2.57 (m, 4H, N–CH₂), 2.10–1.90 (m, 2H, C_{sp}3H), 1.83–1.49 (m, 8H, C_{sp}3H), 1.28–1.04 (m, 5H, CH₂); ¹³C NMR (75.5 MHz, CDCl₃, δ) 159.6 (C_q), 133.4 (CH_{ar}), 116.3 (C_q), 114.2 (CH_{ar}), 86.7 (C_{sp}), 85.9 (C_{sp}), 61.7 (O–CH₃), 55.7 (CH), 50.4 (N–CH₂), 41.8 (CH), 31.1 (CH₂), 30.7 (CH₂), 27.1 (CH₂), 26.6 (CH₂), 23.9 (CH₂). HRMS ESI (M + H)⁺ calcd for C₂₀H₂₈NO⁺, 298.2165; found, 298.2162.

1-(3-(4-Methoxyphenyl)-1-phenylprop-2-yn-1-yl)piperidine 6k.⁴⁹ Pale yellow oil: yield 91% (139 mg); ¹H NMR (200 MHz, CDCl₃, δ) 7.66–7.60 (m, 2H, H_{ar}), 7.45 (d, *J* = 8.9 Hz, 2H, H_{ar}), 7.40–7.28 (m, 3H, H_{ar}), 6.86 (d, *J* = 8.9 Hz, 2H, H_{ar}), 4.77 (s, 1H, CH), 3.82 (s, 3H, CH₃), 2.55 (pt, *J* = 5.2 Hz, 4H, N–CH₂), 1.66–1.53 (m, 4H, CH₂), 1.50–1.40 (m, 2H, CH₂). Spectral data are in good agreement with literature values.

1-(1-Cyclohexyl-3-(3-fluorophenyl)prop-2-yn-1-yl)piperidine 6l.⁵⁰ Pale yellow oil: yield 96% (144 mg); ¹H NMR (200 MHz, CDCl₃, δ) 7.32–7.18 (m, 2H, H_{ar}), 7.17–7.09 (m, 1H), 7.04–6.92 (m, 1H), 3.10 (d, *J* = 9.9 Hz, 1H, CH), 2.68–2.55 (m, 2H, N–CH₂), 2.44–2.32 (m, 2H, N–CH₂), 2.11–1.99 (m, 2H, CH₂), 1.80–1.38 (m, 10H, CH₂), 1.33–0.88 (m, 5H, CH₂). Spectral data are in good agreement with literature values.

4-(1,3-Diphenylprop-2-yn-1-yl)morpholine 6m.⁵¹ Colorless oil: yield 59% (82 mg); ¹H NMR (200 MHz, CDCl₃, δ) 7.68–7.63 (m, 2H, H_{ar}), 7.57–7.50 (m, 2H), 7.44–7.31 (m, 6H), 4.81 (s, 1H, CH), 3.80–3.71 (m, 4H, O–CH₂), 2.74–2.59 (m, 2H, N–CH₂); ¹³C NMR (50.3 MHz, CDCl₃, δ) 138.1 (C_q), 132.0 (CH_{ar}), 128.8 (CH_{ar}), 128.53 (CH_{ar}), 128.45 (CH_{ar}), 128.0 (CH_{ar}), 123.3 (C_q), 88.7 (C_{sp}), 85.3 (C_{sp}), 67.4 (O–CH₂), 62.3 (CH), 50.2 (N–CH₂) (one signal obscured); MS ESI(–) *m/z* (%) = 276.5 (100) [M – H][–], 191.4 (75) [M – morpholine][–]. Spectral data are in good agreement with literature values.

***N,N*-Diethyl-1,3-diphenylprop-2-yn-1-amine 6n.** Colorless oil: yield 57% (75 mg); ¹H NMR (200 MHz, CDCl₃, δ) 7.73 (dd, *J* = 7.4, 0.8 Hz, 2H, H_{ar}), 7.57–7.52 (m, 2H, H_{ar}), 7.43–7.30 (m, 6H, H_{ar}), 5.09 (s, 1H, CH), 2.71–2.53 (m, 4H, N–CH₂), 1.11 (t, *J* = 7.1 Hz, 6H, CH₃); ¹³C NMR (75.5 MHz, CDCl₃, δ) 140.2 (C_q), 132.0 (CH_{ar}), 128.6 (CH_{ar}), 128.5 (CH_{ar}), 128.3 (CH_{ar}), 127.5 (CH_{ar}), 126.7 (C_q), 87.7 (C_{sp}), 86.4 (C_{sp}), 57.3 (CH), 44.8 (N–CH₂), 13.9

(CH₃) (one signal obscured); MS ESI(+) *m/z* (%) = 264.0 (100) [M + H]⁺, 191.4 (20) [M – diethylamine]⁺. HRMS ESI (M + H)⁺ calcd for C₁₉H₂₂N⁺, 264.1747; found, 264.1744.

N,N-Dibenzyl-1,3-diphenylprop-2-yn-1-amine **6o**.^{7a} Colorless oil: yield 61% (118 mg); ¹H NMR (200 MHz, CDCl₃, δ) 7.77 (d, *J* = 7.5 Hz, 2H, H_{ar}), 7.67 (dd, *J* = 6.0, 2.6 Hz, 2H, H_{ar}), 7.52–7.20 (m, 16H, H_{ar}), 4.98 (s, 1H, CH), 3.84 (d, *J* = 13.5 Hz, 2H, N–CH₂), 3.58 (d, *J* = 13.5 Hz, 2H, N–CH₂). Spectral data are in good agreement with literature values.

1-(3-Methyl-1-phenylhex-1-yn-3-yl)pyrrolidine **9a**. Colorless oil: yield 33% (40 mg); ¹H NMR (200 MHz, CDCl₃, δ) 7.447–7.39 (m, 2H, H_{ar}), 7.31–7.27 (m, 3H, H_{ar}), 2.79 (t, *J* = 5.9 Hz, 4H, N–CH₂), 1.88–1.48 (m, 8H, CH_{sp3}), 1.43 (s, 3H, CH₃), 0.96 (t, *J* = 7.1 Hz, 3H, CH₃); ¹³C NMR (75.5 MHz, CDCl₃, δ) 132.0 (CH_{ar}), 128.4 (CH_{ar}), 127.9 (CH_{ar}), 123.9 (C_q), 91.7 (C_{sp}), 84.6 (C_{sp}), 58.2 (C_q), 48.0 (N–CH₂), 44.1 (CH₂), 26.1 (CH₃), 23.9 (CH₂), 18.0 (CH₂), 14.8 (CH₃); MS ESI(+) *m/z* (%) = 264.1 (10) [M + Na]⁺, 242.1 (75) [M + H]⁺, 171.0 (100) [M – pyrrolidine]⁺. HRMS ESI (M + H)⁺ calcd for C₁₇H₂₄N⁺, 242.1903; found, 242.1899.
